Description**Technical Field of the Invention**

5 [0001] Biological systems allow template-directed synthesis of α -peptides. The present invention enables a system that allows template-directed synthesis of other types of polymers as well as α -peptides. The present invention relates to templated molecules and templated molecules linked to a predetermined template. The templated molecules comprise a sequence of functional groups that are linked together. Each functional group is initially linked to an element capable of complementing a predetermined coding element of the template. Following complementation of a coding element, or
 10 complementation of a plurality of coding elements, the appended functional groups are linked and the templated molecule is formed.

Background

15 [0002] The central dogma in biology describes the flow of information as a one-way process from DNA to RNA to polypeptide. Accordingly, DNA is transcribed by a RNA polymerase into mRNA; and the mRNA is subsequently then translated into protein by the ribosomes and tRNAs.

[0003] The direct relation between the DNA and the protein, i.e., the fact that the sequence of triplet codons defines the sequence of α -amino acid residues in a polypeptide, has allowed the development of numerous molecular biological methods, in which the experimenter manipulates the DNA (mutagenizes, recombines, deletes, inserts, etc), and then uses in vivo systems (e.g., microbes) or in vitro systems (e.g., Zubay in vitro expression systems) to transfer the resulting changes from the DNA level to the level of the templated polypeptide, i.e., to mutate, recombine, delete, insert, etc. the polypeptide.

[0004] Several systems have been invented that allows a flow of information from polypeptide to DNA. These systems are phage display, ribosome/polysome display, peptides-on-plasmid display, and other systems. These systems introduce a physical link between the template (e.g., DNA) and the templated molecule (polypeptide). As a result, it is possible, from a population of templated molecules linked to the template that templated the synthesis of the molecule, to first enrich for a desired characteristic of the templated molecule (e.g., binding of the templated molecule to an affinity column), and then amplify the enriched population of templated molecules through amplification of its template (DNA or RNA),
 30 followed by translation of the amplified templates. These methods have been used to identify polypeptides with novel and/or improved features from libraries consisting of from a million to about 10^{15} polypeptides.

[0005] The critical feature of the prior art systems is the amplifiability of the templated molecule, through amplification of its template. Thus, after the selection step in which molecules with the desired property are enriched, the enriched population may be amplified and then taken through yet a selection step, etc. - the process of selection-and-amplification may be repeated many times. In this way the "noise" of the selection assay is averaged out over several selection-and-amplification rounds, and even if the individual selection step only enriches e.g. 10-fold, a theoretical enrichment of 10^{12} can be reached after 12 selection-and-amplification rounds. Had the molecules not been amplifiable, the same enrichment would have had to be achieved in a single screening step, which means that the enrichment in this one step would have had to be 10^{12} , and the assay should still have the same overall stringency (accuracy). This is practically impossible
 40 with current technologies.

[0006] In the field of chemistry, a different combinatorial approach has been developed. This approach involved the parallel synthesis of millions of related compounds, in an array (where each position defined a specific compound), or on beads (where one bead carried many copies of the same compound). The population of compounds were then screened for desired characteristics. Importantly, this type of combinatorial library has no means for amplification, and therefore requires the use of very stringent screening methods, as explained above. Recently, the trend in for example medicinal chemistry has therefore been to use less diverse, but better characterized libraries.

[0007] Principles for tagging chemical libraries have also been developed. For example, systems that employed DNA oligos to tag molecule libraries have been developed as exemplified herein below. The tag is used as a means of identification, but cannot be used to template the synthesis of the tagged molecule. Therefore, despite the tag, these systems still require a very efficient screening method.

[0008] The below listed references illustrate some of the above-mentioned short-comings of the prior art methods in the field of the invention.

[0009] EP 0 604 552 B1 relates to a method for synthesizing diverse collections of oligomers. The invention involves the use of an identifier tag to identify the sequence of monomers in an oligomer. The identifier tags facilitate subsequent identification of reactions through which members of a library of different synthetic compounds have been synthesised in a component by component fashion.

[0010] EP 0 643 778 B1 relates to encoded combinatorial chemical libraries. Each of a collection of polypeptides is labelled by an appended "genetic" tag, itself constructed by chemical synthesis, to provide a "retro-genetic" way of

specifying each polypeptide.

[0011] EP 0 773 227 A1 relates to a method for preparing a new pharmaceutical drug or diagnostic reagent, which includes the step of screening, against a ligand or receptor, a library of different synthetic compounds obtainable by synthesis in a component by component fashion.

[0012] US 4,863,857 relates to a method for determining the amino acid sequence of a polypeptide complementary to at least a portion of an original peptide or protein. In one aspect the method involves: (a) determining a first nucleotide sequence of a first nucleic acid coding for the biosynthesis of at least a portion of the original peptide or protein; (b) ascertaining a second nucleotide sequence of a second nucleic acid which base-pairs with the first nucleotide sequence of the first nucleic acid, the first and second nucleic acids pairing in antiparallel directions; and (c) determining the amino acid sequence of the complementary polypeptide by the second nucleotide sequence when read in the same reading frame as the first nucleotide sequence.

[0013] US 5,162,218 relates to polypeptide compositions having a binding site specific for a particular target ligand and further having an active functionality proximate the binding site. The active functionality may be a reporter molecule, in which case the polypeptide compositions are useful in performing assays for the target ligand. Also disclosed are methods for preparing polypeptides having active functionalities proximate their binding site, said method comprising the step of combining the polypeptide specific for the target ligand with an affinity label having a reactive group attached thereto. The reactive group is then covalently attached to an amino acid side chain proximate the binding site and cleaved from the substrate. The substrate is subsequently eluted, leaving a moiety of the reactive group covalently attached to the polypeptide. The active functionality may then be attached to the moiety.

[0014] US 5,270,170 relates to a random peptide library constructed by transforming host cells with a collection of recombinant vectors that encode a fusion protein comprised of a DNA binding protein and a random peptide and also encode a binding site for the DNA binding protein. The fusion protein can be used for screening ligands. The screening method results in the formation of a complex comprising the fusion protein bound to a receptor through the random peptide ligand and to the recombinant DNA vector through the DNA binding protein.

[0015] US 5,539,082 relates to a novel class of compounds, known as peptide nucleic acids capable of binding complementary ssDNA and RNA strands more strongly than a corresponding DNA. The peptide nucleic acids generally comprise ligands such as naturally occurring DNA bases attached to a peptide backbone through a suitable linker.

[0016] US 5,574,141 relates to functionalized carrier materials for the simultaneous synthesis and direct labeling of oligonucleotides as primers for template-dependent enzymatic nucleic acid syntheses. The polymeric carriers are loaded with nucleic acid building blocks which in turn contain labelling groups or precursors thereof. The polymeric carrier loaded in this way serves as a solid or liquid phase for the assembly of oligonucleotides which can be used as primers for a template-dependent enzymatic nucleic acid synthesis such as in sequencing analysis or in the polymerase chain reaction (PCR).

[0017] US 5,573,905 relates to an encoded combinatorial chemical library comprised of a plurality of bifunctional molecules having both a chemical polymer and an identifier oligonucleotide sequence that defines the structure of the chemical polymer. Also described are the bifunctional molecules of the library, and methods of using the library to identify chemical structures within the library that bind to biologically active molecules in preselected binding interactions.

[0018] US 5,597,697 relates to a screening assay for inhibitors and activators of RNA and DNA-dependent nucleic acid polymerases. The invention provides methods for the identification and discovery of agents which are inhibitors and activators of RNA and DNA-dependent nucleic acid polymerases. The essential feature of the invention is the incorporation of a functional polymerase binding site sequence (PBS) into a nucleic acid molecule which is chosen for its ability to confer a discernible characteristic via its sequence specific activity such that the incorporation of the PBS renders the nucleic acid molecule a functional template for a predetermined RNA or DNA-template directed nucleic acid polymerase. In the presence of the polymerase, suitable primer molecules, and any necessary accessory molecules, catalytic extension of the strand of nucleic acids complementary to the template occurs, resulting in a partial or total elimination of (or increase in) the characteristic conferring activity of the reporter-template molecule described due to the antisense effects of the complementary strand or other polymerase-mediated effects.

[0019] US 5,639,603 relates to a method for synthesizing and screening molecular diversity by means of a general stochastic method for synthesizing compounds. The method can be used to generate large collections of tagged compounds that can be screened to identify and isolate compounds with useful properties.

[0020] US 5,698,685 relates to a morpholino-subunit combinatorial library and a method for generating a compound capable of interacting specifically with a selected macromolecular ligand. The method involves contacting the ligand with a combinatorial library of oligomers composed of morpholino subunits with a variety of nucleobase and non-nucleobase side chains. Oligomer molecules that bind specifically to the receptor are isolated and their sequence of base moieties is determined. Also disclosed is a combinatorial library of oligomers useful in the method and novel morpholino-subunit polymer compositions.

[0021] US 5,708,153 relates to a method for synthesizing diverse collections of tagged compounds by means of a general stochastic method for synthesizing random oligomers on particles. A further aspect of the invention relates to

the use of identification tags on the particles to facilitate identification of the sequence of the monomers in the oligomer.

[0022] US 5,719,262 relates to a novel class of compounds, known as peptide nucleic acids, which bind complementary DNA and RNA strands more strongly than the corresponding DNA or RNA strands, and exhibit increased sequence specificity and solubility. The peptide nucleic acids comprise ligands selected from a group consisting of naturally-occurring nucleobases and non-naturally-occurring nucleobases attached to a polyamide backbone, and contain alkylamine side chains.

[0023] US 5,721,099 relates to encoded combinatorial chemical libraries encoded with tags. Encoded combinatorial chemistry is provided, whereby sequential synthetic schemes are recorded using organic molecules, which define choice of reactant, and stage, as the same or different bit of information. Various products can be produced in the multi-stage synthesis, such as oligomers and synthetic non-repetitive organic molecules. Particularly, pluralities of identifiers may be used to provide a binary or higher code, so as to define a plurality of choices with only a few detachable tags. The particles may be screened for a characteristic of interest, particularly binding affinity, where the products may be detached from the particle or retained on the particle. The reaction history of the particles which are positive for the characteristic can be determined by the release of the tags and analysis to define the reaction history of the particle.

[0024] US 5,723,598 relates to an encoded combinatorial chemical library comprised of a plurality of bifunctional molecules having both a chemical polymer and an identifier oligonucleotide sequence that defines the structure of the chemical polymer. Also described are the bifunctional molecules of the library, and methods of using the library to identify chemical structures within the library that bind to biologically active molecules in preselected binding interactions.

[0025] US 5,770,358 relates to tagged synthetic oligomer libraries and a general stochastic method for synthesizing random oligomers. The method can be used to synthesize compounds to screen for desired properties. The use of identification tags on the oligomers facilitates identification of oligomers with desired properties.

[0026] US 5,786,461 relates to peptide nucleic acids having amino acid side chains. A novel class of compounds, known as peptide nucleic acids, bind complementary DNA and RNA strands more strongly than the corresponding DNA or RNA strands, and exhibit increased sequence specificity and solubility. The peptide nucleic acids comprise ligands selected from a group consisting of naturally-occurring nucleobases and non-naturally-occurring nucleobases attached to a polyamide backbone, and contain alkylamine side chains.

[0027] US 5,789,162 relates to a method for synthesizing diverse collections of oligomers. A general stochastic method for synthesizing random oligomers on particles is disclosed. A further aspect of the invention relates to the use of identification tags on the particles to facilitate identification of the sequence of the monomers in the oligomer.

[0028] US 5,840,485 relates to topologically segregated, encoded solid phase libraries. Libraries of synthetic test compounds are attached to separate phase synthesis supports that also contain coding molecules that encode the structure of the synthetic test compound. The molecules may be polymers or multiple nonpolymeric molecules. The synthetic test compound can have backbone structures with linkages such as amide, urea, carbamate (i.e., urethane), ester, amino, sulfide, disulfide, or carbon-carbon, such as alkane and alkene, or any combination thereof. The synthetic test compound can also be molecular scaffolds, or other structures capable of acting as a scaffolding. The invention also relates to methods of synthesizing such libraries and the use of such libraries to identify and characterize molecules of interest from among the library of synthetic test compounds.

[0029] US 5,843,701 relates to systematic polypeptide evolution by reverse translation and a method for preparing polypeptide ligands of target molecules wherein candidate mixtures comprised of ribosome complexes or mRNA:polypeptide copolymers are partitioned relative to their affinity to the target and amplified to create a new candidate mixture enriched in ribosome complexes or mRNA:polypeptide copolymers with an affinity to the target.

[0030] US 5,846,839 relates to a method for hard-tagging an encoded synthetic library. Disclosed are chemical encryption methods for determining the structure of compounds formed in situ on solid supports by the use of specific amine tags which, after compound synthesis, can be deencrypted to provide the structure of the compound found on the support.

[0031] US 5,922,545 relates to methods and compositions for identifying peptides and single-chain antibodies that bind to predetermined receptors or epitopes. Such peptides and antibodies are identified by methods for affinity screening of polysomes displaying nascent peptides.

[0032] US 5,958,703 relates to methods for screening libraries of complexes for compounds having a desired property such as the capacity to bind to a cellular receptor. The complexes in such libraries comprise a compound under test, a tag recording at least one step in synthesis of the compound, and a tether susceptible to modification by a reporter molecule. Modification of the tether is used to signify that a complex contains a compound having a desired property. The tag can be decoded to reveal at least one step in the synthesis of such a compound.

[0033] US 5,986,053 relates peptide nucleic acid complexes of two peptide nucleic acid strands and one nucleic acid strand. Peptide nucleic acids and analogues of peptide nucleic acids are used to form duplex, triplex, and other structures with nucleic acids and to modify nucleic acids. The peptide nucleic acids and analogues thereof also are used to modulate protein activity through, for example, transcription arrest, transcription initiation, and site specific cleavage of nucleic acids.

[0034] US 5,998,140 relates to methods and compositions for forming complexes intracellularly between dsDNA and

oligomers of heterocycles, aliphatic amino acids, particularly omega-amino acids, and a polar end group. By appropriate choice of target sequences and composition of the oligomers, complexes are obtained with low dissociation constants.

[0035] US 6,060,596 relates to an encoded combinatorial chemical library comprised of a plurality of bifunctional molecules having both a chemical polymer and an identifier oligonucleotide sequence that defines the structure of the chemical polymer. Also described are the bifunctional molecules of the library, and methods of using the library to identify chemical structures within the library that bind to biologically active molecules in preselected binding interactions.

[0036] US 6,080,826 relates to Template-directed ring-closing metathesis and ring-opening metathesis polymerization of functionalized dienes. Functionalized cyclic olefins and methods for making the same are disclosed. Methods include template-directed ring-closing metathesis ("RCM") of functionalized acyclic dienes and template-directed depolymerization of functionalized polymers possessing regularly spaced sites of unsaturation. Although the template species may be any anion, cation, or dipolar compound, cationic species, especially alkali metals, are preferred. Functionalized polymers with regularly spaced sites of unsaturation and methods for making the same are also disclosed. One method for synthesizing these polymers is by ring-opening metathesis polymerization ("ROMP") of functionalized cyclic olefins.

[0037] US 6,127,154 relates to compounds which possess a complementary structure to a desired molecule, such as a biomolecule, in particular polymeric or oligomeric compounds, which are useful as in vivo or in vitro diagnostic and therapeutic agents are provided. Also, various methods for producing such compounds are provided.

[0038] US 6,140,493 relates to a method for synthesizing diverse collections of oligomers. A general stochastic method for synthesizing random oligomers is disclosed and can be used to synthesize compounds to screen for desired properties. Identification tags on the oligomers facilitates identification of oligomers with desired properties.

[0039] US 6,140,496 relates to building blocks for preparing oligonucleotides carrying non-standard nucleobases that can pair with complementary non-standard nucleobases so as to fit the Watson-Crick geometry. The resulting base pair joins a monocyclic six membered ring pairing with a fused bicyclic heterocyclic ring system composed of a five member ring fused with a six member ring, with the orientation of the heterocycles with respect to each other and with respect to the backbone chain analogous to that found in DNA and RNA, but with a pattern of hydrogen bonds holding the base pair together different from that found in the AT and GC base pairs (a "non-standard base pair").

[0040] US 6,143,497 relates to a method for synthesizing diverse collections of random oligomers on particles by means of a general stochastic method. Also disclosed are identification tags located on the particles and used to facilitate identification of the sequence of the monomers in the oligomer.

[0041] US 6,165,717 relates to a general stochastic method for synthesizing random oligomers on particles. Also disclosed are identification tags located on the particles to facilitate identification of the sequence of the monomers in the oligomer.

[0042] US 6,175,001 relates to functionalized pyrimidine nucleosides and nucleotides and DNA's incorporating same. The modified pyrimidine nucleotides are derivatized at C5 to contain a functional group that mimics the property of a naturally occurring amino acid residues. DNA molecules containing the modified nucleotides are also provided.

[0043] US 6,194,550 B1 relates to systematic polypeptide evolution by reverse translation, in particular a method for preparing polypeptide ligands of target molecules wherein candidate mixtures comprised of ribosome complexes or mRNA:polypeptide co-polymers are partitioned relative to their affinity to the target and amplified to create a new candidate mixture enriched in ribosome complexes or mRNA:polypeptide copolymers with an affinity to the target.

[0044] US 6,207,446 B1 relates to methods and reagents for the selection of protein molecules that make use of RNA-protein fusions.

[0045] US 6,214,553 B1 relates to methods and reagents for the selection of protein molecules that make use of RNA-protein fusions.

[0046] WO 91/05058 relates to a method for the cell-free synthesis and isolation of novel genes and polypeptides. An expression unit is constructed onto which semi-random nucleotide sequences are attached. The semi-random nucleotide sequences are first transcribed to produce RNA, and then translated under conditions such that polysomes are produced. Polysomes which bind to a substance of interest are then isolated and disrupted; and the released mRNA is recovered. The mRNA is used to construct cDNA which is expressed to produce novel polypeptides.

[0047] WO 92/02536 relates to a method for preparing polypeptide ligands of target molecules wherein candidate mixtures comprised of ribosome complexes or mRNA:polypeptide copolymers are partitioned relative to their affinity to the target and amplified to create a new candidate mixture enriched in ribosome complexes or mRNA:polypeptide copolymers with an affinity to the target.

[0048] WO 93/03172 relates to a method for preparing polypeptide ligands of target molecules wherein candidate mixtures comprised of ribosome complexes or mRNA:polypeptide copolymers are partitioned relative to their affinity to the target and amplified to create a new candidate mixture enriched in ribosome complexes or mRNA:polypeptide copolymers with an affinity to the target.

[0049] WO 93/06121 relates to a general stochastic method for synthesizing random oligomers on particles. Also disclosed are identification tags located on the particles to facilitate identification of the sequence of the monomers in the oligomer.

[0050] WO 00/47775 relates to a method for generating RNA-protein fusions involving a high-salt post-translational step.

[0052] WO 02/074929 provides methods, compositions, and systems for synthesizing, selecting, amplifying, and evolving non-natural molecules based on nucleic acid templates. The sequence of a nucleic acid template is used to direct the synthesis of non-natural molecules such as unnatural polymers and small molecules. Using this method combinatorial libraries of these molecules can be prepared and screened. Upon selection of a molecule, its encoding nucleic acid template may be amplified and/or evolved.

[0053] WO 00/61775 relates to a new method of synthesis of biologically active substances of determined structure directly in the cells of living organisms containing specific RNA or DNA molecules of determined sequence.

[0054] Walder et al. (1979) [PNAS; vol. 76, no. 1, pp. 51-55] proposes a method for peptide synthesis based on a template-directed scheme that involves peptide bond formation facilitated by juxtaposition of aminoacyl and peptidyl oligonucleotide carriers bound adjacent to one another on an oligonucleotide template.

[0055] Keiler et al. (1996) [Science; vol. 271, pp. 990-993] discloses that variants of lambda repressor and cytochrome b562 translated from messenger RNAs without stop codons could be modified by carboxyl terminal addition of an ssrA-encoded peptide tag and subsequently degraded by carboxyl terminal-specific proteases in E. coli.

[0056] DE 196 46 372 C discloses compounds comprising a structural unit A (genotype) and a further structural unit B (phenotype), in which the genotype and phenotype are permanently linked to each other.

[0057] WO 93/03172 discloses a method for preparing polypeptide ligands of target molecules wherein candidate mixtures comprised of ribosome complexes or mRNA-polypeptide co-polymers are partitioned relative to their affinity for the target and amplified to create a new candidate mixture enriched in ribosome complexes or mRNA-polypeptide co-polymers with an affinity for the target in question.

[0058] Brenner et al. (1992) [PNAS; vol. 89, no. 12, pp. 5381-5383] discloses a method for encoded combinatorial chemistry.

Summary of the Invention

[0059] The present invention solves in a general way the above-mentioned problems and short-comings of the prior art. The invention relates to a system for templating molecules in general, such as polymers, and the template enables templated synthesis of the polymers, allowing in preferred embodiments amplification of the polymer. The system therefore has the same overall characteristics as the natural system (information flow from template to templated molecule), as well as the characteristics of the recently invented ribosome-mediated systems (e.g., phage display), namely the physical link between template and templated molecule. However, the present invention does not involve ribosomes or tRNAs, and therefore allows templating of a wide array of different polymers, including polymers that cannot be synthesised in a natural system based on ribosome-mediated translation of nucleic acids.

[0060] The templating process of the invention has significant advantages over the prior art. As the amplification of the recovered molecules (i.e., their templates) can be done by a parallel process in which all the recovered templates

are present in the same compartment (e.g., reagent tube or microtiter-plate well), and where the molecules are proportionately amplified, no human intervention such as sequencing of the individual molecules is necessary. This is a huge advantage since a typical recovery after a first selection round involves e.g. 10^{10} different molecules, when the starting material is a library of e.g. 10^{15} molecules. When working with such high numbers of molecules, it is practically impossible

to "amplify" 10^{10} molecules by copying the molecules one-at-a-time, i.e., to "amplify" the molecules in a serial process. **[0061]** The present invention generally relates to templated molecules and complexes comprising such molecules linked to a template that has directed the template-directed synthesis of the templated molecule. In one aspect, the templated molecules and the complexes are obtainable according to the methods of the present invention.

[0062] The present invention also discloses methods for synthesizing such templated molecules and/or complexes, methods for targeting such molecules and/or complexes to a target species. The templated molecules are preferably synthesised from building blocks comprising a functional entity comprising a functional group and reactive group capable of covalently linking functional groups and forming a templated molecule. The functional entity of a building block is separated from a complementing element by a cleavable linker, or a selectively cleavable linker. The complementing element is capable of complementing a predetermined coding element of the template, thus ensuring a one-to-one relationship between a coding element - or a complementing element - and a functional entity, or a functional group.

[0063] Also disclosed are methods for identifying the sequence of functional groups of a templated molecule, as well as methods for therapy and diagnostic methods exploiting the templated molecules according to the invention.

[0064] The methods of the invention do not involve ribosome mediated translation of ribonucleic acids. Also, when the templated molecules are peptides comprising either i) exclusively α -amino acids, or ii) substantially exclusively naturally occurring amino acids, such as at least 80 percent, for example 90 percent, such as 95 percent, naturally occurring amino acids, the template does not comprise or essentially consist of a ribonucleic acid.

[0065] A template denotes a sequence of coding elements, wherein each coding element is linked to a neighbouring coding element. A complementing template denotes a sequence of complementing elements, wherein each complementing element is linked to neighbouring complementing element.

[0066] Following complementation of a coding element by a complementing element, or complementation of a plurality of coding elements by a plurality of complementing elements, each complementing element will define an appended functional group capable of being linked - without forming part of the complementing template itself - to a neighbouring functional group defined by a neighbouring complementing element. Accordingly, in one preferred embodiment, the functional group does not participate in the complementation of a coding element in so far as no direct reaction or hybridization takes place between the coding element and the functional group. The term "reaction" means any reactive contact that results in the formation of an interaction - covalent or non-covalent - between the functional group and the coding element. In another embodiment, the functional group of a templated molecule forms part of the complementing template.

[0067] As each complementing element is capable of recognising a predetermined coding element of a template, and as each coding element in turn defines a predetermined functional group, the sequence of coding elements of the template will template the synthesis of the templated molecule comprising a predetermined sequence of covalently linked functional groups.

[0068] According to preferred embodiments of the present invention, it is possible

i) to link a templated molecule comprising a plurality of functional groups to the template that templated the synthesis of the templated molecule,

ii) to link neighbouring functional groups simultaneously with the complementation of neighbouring coding elements by complementing elements defining said functional groups,

iii) to link neighbouring functional groups after the complementation of neighbouring coding elements by complementing elements defining said functional groups,

iv) to link neighbouring functional groups simultaneously with the formation of a complementing template,

v) to link neighbouring functional groups after the formation of a complementing template,

vi) to cleave one or more links between complementing elements of a complementing template without cleaving links between functional groups of a templated molecule, and vice versa, and

vii) to cleave the at least one linker separating the at least one functional entity from the at least one complementing element of a building block without cleaving the complementing template,

viii) to cleave the at least one linker separating the at least one functional entity from the at least one complementing element of a building block without cleaving the link between the functional groups of the templated molecule, and

ix) to cleave the at least one linker separating the at least one functional entity from the at least one complementing element of a building block without cleaving the complementing template and without cleaving the link between the functional groups of the templated molecule.

[0069] Provided that complementation of neighbouring coding elements is achieved, the neighbouring, functional groups of the templated molecule are capable of being linked irrespective of whether a complementing template is formed. Also, it is possible to link neighbouring functional groups and subsequently cleave the cleavable linker separating the functional entity from the complementing element defining said functional entity without cleaving the link between neighbouring functional groups of a templated molecule. Cleavable linkers are cleavable under conditions wherein a selectively cleavable linker is not cleavable. Accordingly, it is possible to cleave the cleavable linkers linking complementing elements and functional groups in a templated molecule without at the same time cleaving selectively cleavable linkers linking - in the same templated molecule - a subset of complementing elements and functional groups. It is thus possible to obtain a complex comprising a templated molecule and the template that has directed the template-mediated synthesis of the templated molecule, wherein the template and the templated molecule are linked by one or more, preferably one, selectively cleavable linker(s).

[0070] The generation of additional templated molecules can be directed by the template without any need for sequencing or any other form of characterisation. This is not possible using prior art "tags" generated by step-by-step synthesis. Accordingly, the complexes of the invention comprising a templated molecule linked to a template makes it possible to rapidly select and amplify desirable, templated molecules.

[0071] In a first aspect, the present invention provides a method for synthesising a templated molecule comprising a plurality of functional groups, said method comprising the steps of

i) providing at least one template comprising a sequence of n coding elements, wherein each coding element comprises at least one recognition group capable of recognising a predetermined complementing element, and wherein n is an integer of more than 1,

ii) providing a plurality of building blocks, wherein each building block comprises

a) at least one complementing element comprising at least one recognition group capable of recognising a predetermined coding element,

b) at least one functional entity comprising at least one functional group and at least one reactive group, and

c) at least one linker separating the at least one functional entity from the at least one complementing element,

iii) contacting each of said coding elements with a complementing element capable of recognising said coding element,

iv) optionally, obtaining a complementing element, and

v) obtaining a templated molecule comprising covalently linked, functional groups by linking, by means of a reaction involving reactive groups, a functional group of at least one functional entity to a functional group of another, functional entity,

wherein the templated molecule is capable of being linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, and

wherein the synthesis of the templated molecule does not involve ribosome mediated translation of a nucleic acid.

[0072] In another aspect, the present invention relates to a templated molecule, a plurality of the same or different templated molecules, wherein preferably each of the templated molecules are obtainable by a method for synthesizing templated molecules according to the present invention.

[0073] As the templated molecule and the template are separate entities capable of being linked by a single linker, the invention also relates to complexes comprising a templated molecule linked to the template that templated the synthesis of the templated molecule. The template capable of templating the synthesis of the templated molecule comprises either a sequence of coding elements, or a sequence of complementing elements, in which case the template is a complementing

template. Accordingly, it is possible to cleave links between functional groups of a templated molecule without cleaving a complementing template or template that templated the synthesis of the templated molecule.

[0074] In another aspect there is provided a method for synthesising a complex comprising a templated molecule linked to the template that templated the synthesis of the templated molecule, wherein the templated molecule and the complex comprising the templated molecule linked to the template that templated the synthesis of the templated molecule are obtainable by the method for synthesis thereof according to the invention.

[0075] In further aspects of the invention there is provided a composition comprising a plurality of templated molecules, wherein each or at least some of the templated molecules are linked to the template that templated the synthesis of the templated molecule, in which case there is provided a plurality of complexes each comprising a templated molecule linked to the template that templated the synthesis of the templated molecule. The compositions may also comprise a templated molecule and - unlinked thereto - the template that templated the synthesis of the templated molecule.

[0076] The amplifiability of the templated molecules of a library provides a library with a unique feature. This unique feature involves e.g. that a huge number of templated molecules can be screened by taking the library through repetitive processes of selection-and-amplification, in a parallel process where the library of molecules is treated as a whole, and where it is not necessary to characterise individual molecules (or even the population of molecules) between selection-and-amplification rounds.

[0077] It is possible according to various preferred embodiments of the invention to screen e.g. more than or about 10^3 different templated molecules, such as more than or about 10^4 different templated molecules, for example more than or about 10^5 different templated molecules, such as more than or about 10^6 different templated molecules, for example more than or about 10^7 different templated molecules, such as more than or about 10^8 different templated molecules, for example more than or about 10^9 different templated molecules, such as more than or about 10^{10} different templated molecules, for example more than or about 10^{11} different templated molecules, such as more than or about 10^{12} different templated molecules, for example more than or about 10^{13} different templated molecules, such as more than or about 10^{14} different templated molecules, for example more than or about 10^{15} different templated molecules, such as more than or about 10^{16} different templated molecules, for example more than or about 10^{17} different templated molecules, such as more than or about 10^{18} different templated molecules.

[0078] As one may perform many repetitive rounds of parallel selection and parallel amplification processes, it is possible to enrich only e.g. 100 fold in each round, and still get a very efficient enrichment, of e.g. 10^{14} fold over a number of selection-and-amplification rounds (theoretically a 10^{14} fold enrichment is obtained after seven rounds each enriching 100 fold). To obtain a similar enrichment of 10^{14} fold using a non-amplifiable library, would require screening conditions allowing 10^{14} fold enrichment in one "round" - and this is not practically possible using state-of-the-art screening technologies. The templated molecules and/or the templates can furthermore be bound to a solid or semi-solid support.

[0079] In even further aspects the methods of the invention - individually or as a combination - relates to a method for screening a composition of complexes or templated molecules potentially having a predetermined activity, a method for assaying the predetermined activity potentially associated with the complexes or the templated molecules, a method for selecting complexes or templated molecules having a predetermined activity, a method for amplifying the template that templated the synthesis of the templated molecule having, or potentially having a predetermined activity, and a method for amplifying the template that templated the synthesis of the templated molecule having, or potentially having, a predetermined activity, said method comprising the further step of obtaining the templated molecule in an at least two-fold increased amount.

[0080] In yet another aspect there is provided a method for altering the sequence of a templated molecule, including generating a templated molecule comprising a novel or altered sequence of functional groups, wherein the method comprises the step of mutating the template that templated the synthesis of the original templated molecule. The method preferably comprises the steps of

i) providing a first template capable of templating the first templated molecule, or a plurality of such templates capable of templating a plurality of first templated molecules,

ii) modifying the sequence of the first template, or the plurality or first templates, and generating a second template, or a plurality of second templates, wherein said second template(s) is capable of templating the synthesis of a second templated molecule, or a plurality of second templated molecules, wherein said second templated molecule(s) comprises a sequence of covalently linked, functional groups that is not identical to the sequence of functional groups of the first templated molecule(s), and optionally

iii) templating by means of said second template(s) a second templated molecule, or a plurality of such second templated molecules.

[0081] The above-mentioned method exploits that a templated synthesis (Figure 1) in one embodiment involves a single-stranded, modifiable intermediate in the form of a template. In the case where this template comprises a nucleotide strand comprising deoxyribonucleotides or ribonucleotides, most molecular biological methods can be applied to modify the template, and therefore to modify the templated polymer.

[0082] The below-mentioned list of molecular biological methods that can be applied to the templated polymers of this invention is therefore far from comprehensive, but merely serves to illustrate that almost any relevant molecular biological method can be applied to the templated polymers as a result of the present invention.

[0083] In cases where nucleotides with non-natural bases are part of the template, some of the molecular biology methodologies may not be applicable. This will primarily depend on the substrate specificity of the enzymes involved (e.g., the Taq DNA polymerase in a PCR reaction; restriction enzyme in USE protocol; etc). Also, methods that involve an in vivo step (e.g., transformation of *E. coli* for amplification of plasmid DNA) may only have a limited feasibility for those nucleotides. Several nucleotides with non-natural bases are, however, known to be incorporated into oligonucleotides by several wildtype and mutant polymerases, and therefore, the use of nucleotides with non-natural bases does not seriously limit the number of in vitro molecular biology methods that can be applied to templated molecules.

Table 1. Molecular Biology applicable to the templated polymers of this invention

-
- In vivo and in vitro amplification, recombination and mutagenesis
 - Kunkel site-directed mutagenesis, using one or multiple (e.g., 50) different mutagenic oligos at below-saturating concentrations, i.e., generating a combinatorial library
 - USE (Unique Site-directed Elimination), using one or multiple (e.g., 50 different mutagenic oligos) at below-saturating concentrations, i.e., generating a combinatorial library
 - PCR (Polymerase Chain Reaction)
 - LCR (Ligase Chain Reaction)
 - PCR shuffling, including family shuffling (shuffling sequences containing blocks with particular homology), and directed shuffling where oligos are spiked into the reaction to direct the shuffling process in a certain direction
 - Other types of shuffling, e.g. homologous recombination in yeast; shuffling protocols as developed at the companies Phyllos, Energy Biosystems, Diversa and by Frances Arnold.
 - Cassette mutagenesis
 - Other polymerase- or PCR-based methods, e.g., overlap extension, gene synthesis, and error-prone PCR
 - Chemical or UV-induced mutagenesis
 - Wildtype or variant template synthesis and translation into templated polymer (wildtype in this respect means the template sequence that will template the synthesis of the known ("wildtype") polymer; variant in this respect means a partly randomised or spiked template sequence that will template the synthesis of a variant of the known polymer)
 - Specific cleavage by restriction enzymes
 - Ligation by DNA or RNA ligases; "gene splicing"
 - Affinity selections (using the template-templated polymer complex)
 - Sequencing
 - Arraying the polymers on "DNA chips", by using the template as a tag that binds a DNA array

[0084] Instead of isolating the (underivatized) template strand, it may be desirable to apply the molecular biological methods to either the template-complementing template double-helix or to the derivatized complementing template. The derivatized template may at this point contain unpolymerized functional entities; polymerized functional entities; or a trace left behind from the cleaving of the linker that connected the functional entity and the complementing element. Many polymerases and other enzymes are known to accept DNA- or RNA-templates with a high degree of derivatization. Therefore, many in vitro methods involving polymerases and other enzymes are likely to be feasible using the (derivatized) complementing template as starting point. It will primarily depend on the substrate- or template specificity of the enzymes involved whether it will be feasible to use the derivatized complementing template as a starting point for the molecular biological method in question. The skilled person will be capable of evaluating the feasibility of various practical approaches in this respect.

[0085] The present invention also pertains to building blocks used for synthesising the templated molecule and to complexes comprising such building blocks. In another aspect there is provided the use of a building block for the synthesis of a templated molecule according to the invention. In a preferred embodiment of this aspect, the templated molecule comprises or essentially consists of a molecular entity capable of binding to another molecular entity in the form of a target molecular entity or a binding partner.

[0086] The templated molecule is preferably a medicament capable of being administered in a pharmaceutically

effective amount in a pharmaceutical composition to an individual and treating a clinical condition in said individual in need of such treatment.

[0087] In other aspects of the invention there are provided a pesticidal composition, an insecticidal composition, a bacteriocidal composition, and a fungicidal composition, as well as methods for preparing such compositions and uses thereof, wherein each of said compositions comprise a templated molecule according to the invention in an amount effective to achieve a desired effect.

[0088] In still further aspects there is provided a method for identifying a pharmaceutical agent, or a diagnostic agent, wherein said method comprises the step of screening a plurality of drug targets with at least one predetermined, templated molecule, and identifying a pharmaceutical agent, or a diagnostic agent, in the form of candidate templated molecules capable of interacting with said drug targets.

[0089] In yet another aspect there is provided a method for identifying a target, including a drug target, wherein said method comprises the step of screening a plurality of ligands or receptor moieties with at least one predetermined, templated molecule, and identifying drug targets in the form of ligands or receptor moieties capable of interacting with said templated molecules.

[0090] The present invention also relates to any isolated or purified templated molecule having an affinity for a predetermined target, including a drug target, as well as to targets, including drug targets, in the form of ligands, receptor moieties, enzymes, cell surfaces, solid or semi-solid surfaces, as well as any other physical or molecular entity or surface having an affinity for a predetermined templated molecule.

[0091] In even further aspects of the invention there is provided a method for treatment of an individual in need thereof, said method comprises the step of administering to the individual a pharmaceutically effective amount of a molecule identified by a method of the present invention and having an affinity for a predetermined target, including a drug target.

[0092] In a still further aspect there is provided a method for treatment of an individual in need thereof, said method comprises the step of administering to the individual a pharmaceutically effective amount of an isolated or purified ligand or receptor moiety having an affinity for a predetermined templated molecule according to the invention. The isolated or purified ligand or receptor moiety is preferably identified by the above-mentioned method of identification of the invention.

[0093] The present invention may be performed in accordance with several embodiments. In a first embodiment the step of contacting the complementing element with the coding element involves one or more polymerases or transcriptases. Thus, in accordance with this embodiment the building blocks is a nucleotide derivative. In one aspect of this first embodiment, the building blocks are mononucleotides, however the building blocks may be a di- or oligonucleotides. While mononucleotides are the natural substrate for polymerases and transcriptases, oligonucleotides are incorporable in accordance with the method of WO 01/16366. The mono- or oligonucleotide derivative serves as the complementing element. One or more linker(s) is/are attached at one end to the mono- or oligonucleotide derivative and at the other end to a functional entity. Especially, in the case in which the complementing element is a mononucleotide derivative, it is preferred that the linker is attached so that the functional entity is projecting into the major groove of a double stranded helix to allow adjacent functional entities to form a linkage to each other.

[0094] In a second embodiment of the invention, building blocks comprising an mono- or oligonucleotide as complementing element are chemically ligated together. Several methods for chemical ligation are known in the art, such as the 5'-phosphoimidazolid method (Visscher, J.; Schwartz, A. W. Journal of Molecular Evolution 1988, 28, 3-6. And Zhao, Y.; Thorson, J. S. J. Org. Chem. 1998, 63, 7568-7572) or the 3'-phosphothioate method (Alvarez et al. J. Org. Chem. (1999), 64, 6319-28 Pirrung et al. J. Org. Chem. (1998), 63, 241-46).

[0095] In a third embodiment of the invention, building blocks comprising an oligonucleotide as complementing element is ligated together using a ligase enzyme.

[0096] In a fourth embodiment of the invention, the building blocks comprise an oligonucleotide as complementing element, said oligonucleotide having a sufficient length to adhere to the template without the need for ligation to a primer or an other complementing element.

[0097] The building blocks are in general adapted to the method used for contacting the complementing element with the template and production of the templated molecule. As an example, the linker may be relatively short when a mononucleotide derivative is used, while the linker needs to be considerable longer when an oligonucleotide is used as building block.

Brief Description of the Figures

[0098] The following symbols are used in the following figures to indicate general characteristics of the system: In figures 1, 7C, 8C, 11, 11 ex.1, 12, 13, 14, 14 ex. 1 - 2, 15, 15 ex. 1 - 7, 17, 17 ex. 1, 17, 17 ex. 1 - 2, 19, 19 ex. 1 - 3, 20, 21, and 22A, a long horizontal line symbolizes a template, complementing template or the complex of the template with the complementing template. For clarity, in some of the figures only the polymerization step, not the activation step, has been included. Rx denotes functional groups.

Figure 1. Chemical Display of Templated Molecules - The principle.

[0099] The protocol for the chemical display of templated molecules can be divided into 6 steps, i) incorporation, ii) polymerization, iii) activation, iv) selection/screening, v) amplification, and vi) characterization. Incorporation involves the incorporation of building blocks into the complementing template, which sequence is determined by the template. Incorporation may be mediated by enzymes such as polymerase or ligase. The template comprises primer binding sites at one or both ends (allowing the amplification of the template). The remaining portion of the template may be of random, partly random or predetermined sequence. The complementing elements preferably comprises of a functional entity, a complementing element and a linker connecting the functional entity and the complementing element. Detailed examples of selected complementing elements, their incorporation, polymerization and activation are shown in (Figure 7 and 8).

[0100] Polymerization involves reactions between the incorporated building blocks, thereby forming covalent bonds between the functional entities, in addition to the functional bonds that already exist between the complementing elements. Activation involves cleaving some, all but one, or all of the linkers that connect the sequence of functional entities to the template or complementing template having templated the templated molecule comprising the functional entities. Activation may also involve separating the template and the complementing template without cleaving the linkers connecting the functional entities and the complementing template.

Selection or screening involves enriching the population of template-templated molecule pairs for a desired property.

[0101] Amplification involves producing more of the template-templated molecule pairs, by amplification of the template or complementing template, and producing more of the template-templated molecule pairs, for further rounds of selection/screening, or for sequencing or other characterization.

Cloning and sequencing involves the cloning of the isolated templates or complementing templates, followed by characterization. In some cases, it may be desirable to sequence the population of isolated templates or complementing templates, wherefore cloning of individual sequences are not required.

Figure 2A and 2B. An expanded set of base pairs.

[0102] The figure discloses a set of natural and non-natural base pairs that obeys Watson-Crick hydrogen-bonding rules. The base pairs are disclosed in US 6,037,120, incorporated herein by reference.

Figure 3. A monomer building block.

[0103] A building block comprises or essentially consists of a functional entity, connected through a selectively cleavable linker to a complementing element. Each complementing element has two reactive groups (type I), which may react with two other complementing elements. The complementing element contains a recognition group that interacts with a complementary coding element (coding element not shown). The functional entity in this example comprises or essentially consists of two reactive groups (type II), which may react with reactive groups of other functional entity(ies), and a functional group, also called a functionality. The reactive groups of type II, and the molecular moiety that connects them, will become (part of) the backbone in the resulting encoded polymer.

Figure 4. A monomer building block with only one reactive group type II.

[0104] A building block comprises or essentially consists of a functional entity, connected through a selectively cleavable linker to a complementing element. Each complementing element has two reactive groups (type I), which may react with other complementing elements. The complementing element contains a recognition group that interacts with a complementary coding element (coding element not shown). The functional entity in this example comprises or essentially consists of a reactive group type 11, which may react with reactive groups of other functional entities, and a functional group, also called a functionality. The reactive group type II will become (part of) the backbone in the resulting encoded polymer.

Figure 5. Building blocks and the polymers resulting from template directed incorporation of the building blocks and their polymerization and activation

[0105] Figure 3 discloses a detailed description of features of individual building blocks. Three different complementing elements are shown, each linked to a specific functional entity. The right half of the figure includes the template which directs the incorporation of the building blocks by complementary base pairing.

A). The reactive groups type I of the complementing element react, whereby a part of the reactive group is lost (e.g., PPI in the incorporation of nucleoside triphosphates). In the shown example, the polymerization of reactive groups

type II also results in loss of part of the reactive groups. The backbone of the resulting polymer comprises or essentially consists of part of the original reactive groups type II and the molecular entity that connects the reactive groups. Part of the linker remains attached to the functional entity.

B). The reactive groups type I react as in (A). The reactive groups type II do not react directly, but rather a "bridging molecule" is added. Upon reaction with this bridging molecule, part of the reactive group is lost. The cleavable linker used in this example is a so-called "traceless linker" and therefore the functional entity is released with no trace of the linker molecule.

C). Incorporation in this case does not involve coupling of the individual complementing elements, i.e., does not lead to the reaction of the reactive groups type I. The reactive groups type II react with bridging molecules as in (B).

D). The functional entity contains only one reactive group type II. The reactive group type II reacts with a bridging molecule.

Figure 6. A derivatized nucleotide as building block

[0106] The nucleotide building block comprises or essentially consists of the complementing element (the nucleotide) and a functional entity (in this case a dicarboxylic acid) connected by means of a selectively cleavable linker (here a disulfide). The reactive groups type I of the nucleotide are the triphosphate and the hydroxyl group, as indicated. The recognition group of the nucleotide is the base. The functional entity comprises or essentially consists of a functional group (a hydroxyl), two reactive groups type II (carboxylic acids), and a backbone structure (aromatic ring) connecting the two reactive groups. Finally the linker (disulfide) is cleavable by for example DTT.

A derivatized di-nucleotide as building block

[0107] The complementing element is a modified dA-dU di-nucleotide that comprises the recognition group, in this case the adenine and uracil bases. It is connected to the functional entity (here an amino acid) via a cleavable propargylester linkage. Upon basic cleavage, the linker releases the functional group, a carboxylic acid. The reactive groups of type I of the di-nucleotide are the hydroxyl group and the phosphoro(2-methyl)imidazolidine. Reactive groups of type II are the amino group and the carboxylic acid of the amino acid as indicated.

A derivatized oligo-nucleotide as building block

[0108] The complementing element is the last 20 bases of the oligonucleotide shown. It is linked to the functional entity, a *N*-Boc beta amino acid, via an oligo-nucleotide comprising 40 bases (B is an internal biotin incorporated using the commercially available phosphoramidite (10-1953-95 from Glen research) including a cytosine deoxyribonucleotide that has been modified at the 5'-phosphato group with a mercaptohexane spacer connected to an N-hydroxysuccinimide moiety. Reactive group of type II is the carboxylic acid bound to the oxygen atom of the N-hydroxysuccinimide moiety. It is susceptible to nucleophilic attack by e.g. an amine.

Figure 7. C-terminal tagging of a β -dipeptide - incorporation, polymerization and activation.

[0109]

A) Structures of the primer and two monomer building blocks. The initiator molecule is attached to the 5-position of the 3'-terminal dU of the primer. The initiator is a Fmoc-protected amine. The dUTP-derivative carries a photoprotected hydroxyl group. The hydroxyl group is coupled to the N-thiocarboxyanhydride (NTA) ring structure. The dATP-derivative is modified at the 7 position. A photoprotected amine is coupled to the NTA.

B) The primer (which is annealed to the template, not shown in figure) is extended from its 3'-end through incorporation of the dUTP and dATP by a polymerase. Then the initiator is activated by piperidine, which releases the primary amine. The primary amine attacks the neighboring NTA, which opens the NTA rings structure, releases CSO, and as a result, produces a primary amine. This primary amine now attacks the next NTA unit in the array. As a result, a polymer, attached through its functional groups (OH and NH₂) to the DNA strand, is formed. Finally, the linkers connecting the DNA strand with the NTA units, are cleaved. The resulting polymer in this case is a β -peptide, carrying the functional groups OH and NH₂, encoded by the DNA sequence dUdA. In the shown example, the sequence 5'-dUdA-3' encodes a β -peptide in the C-terminal to N-terminal direction, as opposed to Nature's encoding system where 5' to 3' RNA encodes an α -peptide in the N-to C-terminal direction. The β -peptide is attached to the encoding DNA through its C-terminal end.

C) Schematic representation of the incorporation, polymerisation and activation. The encoded polymer becomes attached to the encoding molecule (DNA) through the initiator molecule.

Figure 8. N-terminal tagging of a β -dipeptide- incorporation, polymerization and activation.**[0110]**

A) Structures of the primer, two monomer building blocks, and an oligo. The initiator molecule is attached to the 5-position of the 3'-terminal U of the primer. The primer is complementary to the upstream part of the template. The initiator is a Fmoc-protected amine. The UTP-derivative carries a photo-protected hydroxyl group. The hydroxyl group is attached to the N-thiocarboxyanhydride (NTA) ring structure. The ATP-derivative is modified at the 7 position. A photo-protected amine is attached to the NTA. The oligo is complementary to the downstream sequence of the template. The oligo carries a reactive thioester attached to the U at the oligo's 5'end. The stability of the thioester in water can be modified as desired by changing the structure of the thioester-component (in the example, the thiol-component is a thiophenol).

B) The primer (which is annealed to the template, not shown in figure) is extended from its 3'-end through incorporation of the UTP and ATP by a polymerase. Then the initiator is activated by piperidine, which releases the primary amine. The primary amine attacks the neighboring NTA, which opens the NTA rings structure, releases CSO, and as a result, produces a primary amine. This primary amine now attacks the next NTA unit in the array. As a result, a polymer, attached through its functional groups (OH and NH_2) to the RNA strand, is formed. Finally, the linkers connecting the RNA strand with the NTA units are cleaved. The resulting polymer is a β -peptide, carrying the functional groups -OH and - NH_2 , encoded by the ribonucleic acid sequence UA. The sequence 5'-UA-3' encodes a β -dipeptide in the N-terminal to C-terminal direction, similar to the way that Nature encodes α -peptides. The β -peptide is attached to the encoding RNA through its N-terminal end.

C) Schematic representation of the incorporation, polymerisation and activation. Upon cleavage of a subset of linkers, the encoded polymer becomes attached to the downstream oligonucleotide.

Figure 9. Nucleotide-derivatives that are known to be incorporated into RNA or DNA strands by DNA or RNA polymerases.**[0111]**

Top: Nucleotide, the four bases and the site of attachment of the molecular moiety (R).

Center: Nucleotides with appendices (R) that are accepted as substrates by polymerases.

Bottom: Nucleotides with appendices (R) that may be used with the present invention. Compound (a) would be used in for example fill-in experiments (see Figure 15). Compound (b) would be used for example in zipping polymerization reactions (see Figure 14 and 14, example 1). Compound (c) would be used for example in ring-opening polymerization reactions (see Figure 18 and 18, example 1).

Figure 10. Cleavable linkers and protection groups.

[0112] Cleavable linkers and protection groups, agents that may be used for their cleavage and the products of cleavage.

Figure 11. Polymerization by reaction between neighboring reactive groups type II.

[0113] For clarity, only the polymerization reaction (and not the activation) is shown in the figure. X represents the reactive groups type II of the functional entity. In this case the two reactive groups type II are identical.

[0114] Polymerization (reaction of X with X to form XX) either happens spontaneously when the monomer building block has been incorporated, or is induced by a change of conditions (e.g. pH), or by the addition of an inducing factor (chemical or UV exposure, for example)

Figure 11 ex.1. Coumarin-based polymerization.

[0115] Light-induced reaction of the coumarin units, followed by activation (cleavage of the linker), results in a polymer backbone of aromatic and aliphatic ring structures. Examples of functional groups (phosphate, carboxylic acid and aniline) are shown.

Figure 12. Polymerization between neighboring non-identical reactive groups type II.

[0116] In this example, X may react with Y but not another X. Likewise, Y does not react with Y. Polymerization can

either happen during the incorporation of building blocks (as shown in the figure), or after incorporation of several building blocks.

Figure 13. Cluster formation in the absence of directional polymerisation.

[0117] When the incorporated monomers are not fixed with regard to rotation about the bond that links the functional entities to the complementing elements, cluster formation may result, as shown in the figure.

This represents a significant problem for longer polymers. The problem may be solved by (i) fixing the incorporated monomers in a preferred orientation which does not allow X and Y (reactive groups type II) to exchange positions in the array (e.g., by coupling the functional entity and the complementing element via a double bond or two bonds, e.g., coupling the functional entity both to the base and the ribose of a nucleotide, or to the two bases of a dinucleotide), (ii) employing directional polymerisation ("zipping", see for example figure 17), or (iii) setting up conditions that ensure that the monomers react during or right after incorporation into the complementing template, i.e., each monomer reacts with the previously incorporated monomer before the next monomer is incorporated (see for example Figure 14, with example).

Figure 14. Zipping-polymerization and simultaneous activation.

[0118] Polymerization results in activation of the polymer. The geometry of the reaction between X and Y is in this example the same for all monomers participating in the polymerization

Figure 14, example 1. Simultaneous incorporation, polymerisation and activation - formation of peptides.

[0119]

(A). Nucleotide derivatives, to which amino acids thioesters have been appended, are incorporated. During or after incorporation of a nucleotide-derivative, the amine attacks the carbonyl of the (previously incorporated) neighboring nucleotide. This results in formation of an amide bond, which extends the peptide one unit. When the next monomer is incorporated, this may attack the thioester carbonyl, resulting in cleavage of the dipeptide from the nucleotide, to form a tripeptide. The process continues further downstream the complementing template, until incorporation of nucleotide derivatives stops. Importantly, the geometry of the nucleophilic attack remains unchanged. As the local concentration of nucleophilic amines is much higher on the template than in solution, reactions in solution is not expected to significantly affect the formation of the correct encoded polymer. Furthermore, the reactivity of the amine with the ester may be tuned in several ways. Parameters that will affect the reactivity include: (i) pH and temperature, (ii) length, point of attachment to the nucleotide, and characteristics (charge, rigidity, hydrophobicity, structure) of the linker that connects the ester and the nucleotide, (iii) nature of ester (thio-, phospho-, or hydroxy-ester); (iv) the nature of the substituent on the sulfur (see (B) below). In addition, the efficiency of correct polymer formation is also affected by the rate of incorporation and rate of reaction once incorporated. The rate of incorporation is determined by k_{cat} and K_m . The k_{cat} and K_m values may be tuned by changing the conditions (pH, concentration of nucleotides, salts, templates and enzymes), by choice of enzyme, or by changing the characteristics of the enzyme by protein engineering. Also, the nature and size of the nucleotide-derivatives may influence its rate of incorporation.

This general scheme involving incorporation, polymerisation and activation during or right after building block incorporation, can be applied to most nucleophilic polymerisation reactions, including formation of various types of peptides, amides, and amide-like polymers (e.g., mono-, di-, tri-, and tetra-substituted α -, β -, γ -, and Ω -peptides, polyesters, polycarbonate, polycarbamate, polyurea), using similar structures.

(B). Four different thioesters with different substituents and therefore different reactivity towards nucleophiles.

Figure 14, example 2. Simultaneous incorporation, polymerization and activation - formation of a polyamine.

[0120] This figure shows a "rolling-circle polymerization reaction" where the chain containing the nucleophilic center attacks the electrophile attached to the DNA-part, using this DNA-part as the leaving group.

Figure 15. "Fill-in" polymerization (symmetric XX monomers).

[0121] Fill-in polymerization by reaction between reactive groups type II ("X" in the figure) and bridging molecules (Y-Y in figure).

For clarity, only the polymerization reaction (not the activation) is shown in the figure. The thick line represents double or single stranded nucleic acid or nucleic acid analog. X represents the reactive groups type II of the functional entity. In this case the two reactive groups type II are identical. (Y-Y) is added to the mixture before, during or after incorporation

of the monomer building blocks. Likewise, significant reaction between X and Y may take place during or after incorporation of the monomers.

Figure 15, ex.1. Poly-imine formation by fill-in polymerization.

[0122] Dialdehyde is added in excess to incorporated diamines. As a result, a poly-imine is formed. In the example, the polymer carries the following sequence of functional groups: cyclopentadienyl, hydroxyl, and carboxylic acid.

Figure 15, example 2. Polyamide formation.

[0123] After incorporation of nucleotides to which have been appended di-amines, EDC (1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide) and dicarboxylic acid is added in excess to the primary amines on the oligonucleotide using standard coupling conditions. Alternatively, a di-(N-hydroxy-succinimide ester) may be added in excess, at a pH of 7-10. As a result, two amide-bonds are formed between two neighboring nucleotide-appendices. After this polymerisation, the appendices are separated from the oligonucleotide backbone (activation), leaving one linker intact, and the protected functional groups are deprotected to expose the functional groups. The final result is a DNA-tagged polyamide.

An alternative route to polyamides would be to incorporate nucleotides to which had been appended di-carboxylic acids, and then add di-amines and EDC, to form amide bonds between individual nucleotides of the oligonucleotide. Alternatively, the nucleotide derivatives might contain N-hydroxy-succinimidyl (NHS) esters, which would react with the added amines without the need to add EDC. Initially, this latter method was considered to be problematic in the case where incorporation is mediated by a polymerase, as the NHS-esters probably would react with amines on the polymerase, potentially inhibiting the activity of the polymerase. However, practical experiments have shown that it is possible to incorporate NHS-derivatised nucleotides.

(A). The backbone of the resulting polymer comprises or essentially consists of amide-bonded aromatic rings. The substituents of this example are a protected primary amine, a branched pentyl group, a tertiary amine and a pyrimidyl. The primary amine is protected in order to avoid its reaction with the dicarboxylic acid. Appropriate protecting groups would be for example Boc-, Fmoc, benzyloxycarbonyl (Z, cbz), trifluoracetyl, phthaloyl, or other amino protecting groups described e.g. in (T. W. Green and Peter G. M. Wuts (1991), Protective Groups in Organic Synthesis).

(B). The backbone comprises or essentially consists of aromatic rings, connected by amide bonds. The substituents are indanyl, diphenylphosphinyl, carboxamidoethyl and guanidylpropyl, the latter two representing the asparagine side chain, and the arginine side chain, respectively. The guanidyl function is protected, as it is more reactive than standard amines. An appropriate protecting group would be Mtr (4-methoxy-2,3,6-trimethylbenzenesulfonyl), Mts (mesitylene-2-sulfonyl) or Pbf (2,2,4,6,7-pentamethyldihydro-benzifuran-5-sulfonyl).

Figure 15, example 3. Polyurea formation.

[0124] The incorporated nucleotide derivatives react with phosgen or a phosgen-equivalent such as CDI to form a polyurea. The linkers are cleaved and the protected hydroxyl is deprotected.

Appropriate leaving groups (Lv) are chloride, imidazole, nitrotriazole, or other good leaving groups commonly employed in organic synthesis

Figure 15, example 4. Chiral and achiral polyurea backbone formation.

[0125] In this example, the functional group Rx is used as a cleavable linker, that generates the desired functional group upon activation. In both (A) and (B), a polyurea is formed.

In (A), the functional group is attached to the backbone via a chiral carbon. The hydrogen on this carbon is drawn to emphasize this. Before polymerisation, there is free rotation about the bond connecting the chiral carbon and the functional group. When the reactive groups type II (the amines) react with the phosgen equivalent (e.g., a carbonyldiimidazole) to form the polymer, the building blocks may be inserted in either of two orientations (as indicated by the position of the hydrogen, left or right). As a result, each residue of the polymer has two possible chiral forms. Therefore, a given encoding molecule will encode a polymer with a specific sequence of residues, but an encoded polymer of 5 or 15 residues will have $2^5 = 32$ or $2^{15} = 32768$ stereoisomers, respectively. In certain cases it may be advantageous to incorporate such additional structural diversity in the library (for example when the polymer is relatively short). In other cases such additional diversity is not desirable, as the screening efficiency may become compromised, or it may become too difficult to deconvolute the structure of a polymer that has been isolated in a screening process, together with the other stereoisomers encoded by the same encoding molecule (for example when the polymer is long).

In (B), the chiral carbon of (A) has been replaced by a nitrogen. As a result, the resulting polymer backbone is achiral,

and the encoding molecule encodes one specific structure.

Figure 15, example 5. Polyphosphodiester formation.

[0126] The incorporated nucleotide derivatives react with the activated phosphodiester to form a polyphosphodiester. Then the linkers are cleaved, resulting in a polyphosphodiester, attached through a linker to the encoding molecule. An example of an appropriate leaving groups (Lv) is imidazole.

Figure 15, example 6. Polyphosphodiester formation with one reactive group type II in each monomer building block.

[0127] Each incorporated nucleotide contains an activated phosphodiester. Upon addition of a dihydroxylated compound such as 1,3-dihydropyridine, a functionalised polyphosphodiester is formed. Finally, the functional groups Rx are liberated from the complementing template by cleavage of the protection groups/cleavable linker that connected them to the oligonucleotide.

Figure 15, example 7. Pericyclic, "fill-in" polymerization.

[0128] After incorporation of the nucleotide-derivatives, 1,4-benzoquinone is added in excess, resulting in the formation of a polycyclic compound. Finally, the polymeric structure is activated by cleaving the linkers that connect the polymer to the nucleotides, except for one (non-cleavable) linker which is left intact.

Figure 16. Encoded "Fill-in".

[0129] Fill-in by encoding is performed by the method depicted. The encoded fill-in moiety is the Y-R_x-Y of the second building block. Using this method it is possible to link two functional entities X-R_x-X by a predetermined functional entity Y-R_x-Y. In some embodiments this may be of advantage because the encoded fill-in functional entity Y-R_x-Y does not have to be the same through out the molecule, as is the case for the method shown in Fig. 15.

Figure 17. "Fill-in" polymerization (asymmetric XS monomers).

[0130] Fill-in polymerization by reaction between reactive groups type II ("X" and "S" in the figure) and bridging molecules (T-Y) in figure).

For clarity, only the polymerization reaction (not the activation) is shown. The thick line represents double or single stranded nucleic acid or nucleic acid analog. X and S represent the reactive groups type II of the functional entity. In this case the two reactive groups type II are non-identical. (T-Y) is added to the mixture before, during or after incorporation of the monomer building blocks. Likewise, significant reaction between X and Y, and between S and T may take place during or after incorporation of the monomers.

Figure 17, example 1. Fill-in polymerization by modified Staudinger ligation and ketone-hydrazide reaction.

[0131] The reactive groups (type II) X and S of the building blocks are azide and hydrazide. The added molecule that fills the gaps between the building blocks carry a ketone and a phosphine moiety. The reactions between a ketone and a hydrazide, and between an azide and a phosphine, are very chemoselective. Therefore, most functional groups Rx can be employed without the need for protection during the polymerization reactions. Examples for the molecular moieties R, R₁, X and Y may be found in (Mahal et al. (1997), Science 276, pp. 1125-1128; Saxon et al. (2000), Organic Letters 2, pp. 2141-2143).

Figure 18. "Zipping" polymerization.

[0132] The initiator molecule (typically located at one of the ends of the nascent polymer) is activated, for example by deprotection or by a change in pH. The initiator then reacts with the reactive group X of the neighbouring monomer. This activates the reactive group Y for attack on the neighbouring X. Polymerisation then travels to the other end of the molecule in a "zipping" fashion, until all the desired monomers have been connected. The activation of the initiator (and reactive groups Y) may be both for attack by it on the neighbouring reactive group, or activation of it for attack by the neighbouring reactive group.

Figure 18, example 1. Radical polymerisation.

[0133] The initiator molecule, an iodide, is activated by the addition of a radical initiator, for example ammonium persulfate, AIBN (azobis-isobutyronitrile) or other radical chain reaction initiators. The radical attacks the neighboring monomer, to form a new radical and a bond between the first two monomers. Eventually the whole polymer is formed, and the polymer may be activated, which simultaneously creates the functional groups Rx.

Figure 18, example 2. Cationic polymerisation.

[0134] A cation is created by the exposure of the array to strong Lewis acid. The double bond of the neighbouring monomer reacts with this cation, whereby the positive charge migrates to the neighbouring monomer. Eventually the whole polymer is formed, and finally it is activated.

Figure 19. Zipping polymerization by ring opening.

[0135] The initiator reacts with the reactive group X in the ring structure, which opens the ring, whereby the reactive group Y in the same functional entity is activated for reaction with a reactive group X in a neighboring functional entity.

Figure 19, example 1. "Zipping" polymerization of N-thiocarboxyanhydrides, to form β -peptides.

[0136] After incorporation of the building blocks, the initiator is deprotected. The primary amine then attacks the carbonyl of the neighbouring N-thiocarboxyanhydride (NTA) unit. As a result, CSO is released, and a primary amine is generated. This amine will now react with the next NTA unit in the array, and eventually all the NTA units will have reacted, to form a β -peptide. Finally, the oligomer is activated.

A number of changes to this set-up can be envisaged. For example, instead of thiocarboxyanhydrides, one might use carboxyanhydrides. The initiator might be protected with a base- or photolabile group. If a base-labile protection group is chosen, the stability of the carboxyanhydride must be considered. At higher pH it may be advantageous to use carboxyanhydrides rather than thiocarboxyanhydrides. Finally, the initiator might be unprotected and for example coupled to the primer. In this case the concentration of the initiator in solution will be very low (typically nanomolar to micromolar), wherefore only an insignificant amount of initiator will react with the carboxyanhydrides. After or during incorporation of the building blocks the local concentration of initiator and carboxyanhydride will be much higher, leading to efficient polymerization.

Other types of peptides and peptide-like polymers (e.g., mono-, di-, tri-, and tetra-substituted α -, β -, γ -, and Ω -peptides, polyesters, polycarbonate, polycarbamate, polyurea) can be made, using similar cyclic structures. For example, α -peptides can be made by polymerization of 5-membered carboxyanhydride rings.

Figure 19, example 2. "Zipping" polymerization of 2,2-diphenylthiazinanone units to form β -peptides.

[0137] The deprotected nucleophile, a primary amine, attacks the carbonyl of the neighboring thioester, thereby forming an amide bond. The released thiol reorganizes, to form a thioketone. As a result a free primary amine is generated, which attacks the carbonyl of a neighboring thioester, etc. Eventually an α -substituted β -peptide is formed, linked through its C-terminal end. The reactivity of the primary amine with the ester may be modified for example by the choice of ester (thioester or regular ester), pH during the polymerization reaction and the choice of substituents on the aromatic ring (s). The relative reactivity of the secondary amine contained in the cyclic moiety and the primary amine released upon ring-opening, may be adjusted by the bulk at the carbon between the secondary amine and the thioester. For example, replacing the two aromatic rings with one aromatic ring will decrease the bulk around the secondary amine, making it more nucleophilic, whereas the nucleophilicity of the primary amine that is formed upon ring-opening is not affected by the bulk at this position. Other peptides and amide-like polymers may be formed by this principle. For example, γ -peptides may be formed by polymerization of 7-membered thiazinanone rings.

Figure 19, example 3. Polyether formation by ring-opening polymerisation.

[0138] The initiator is deprotected by for example base or acid. The formed anion then attacks the epoxide of the neighboring monomer, to form an ether-bond. As a result, an anion is formed in the neighboring unit. This attacks the next monomer in the array, and eventually the full-length polyether has been formed. Depending on the conditions the attack will be at the most or least hindered carbon of the epoxide (under acidic or basic conditions, respectively). In the final step, the encoded polyether is activated. In this case, the polymer is fully released from the encoding molecule. The screening for relevant characteristics (e.g., effect in a cell-based assay or enzymatic activity) may be performed in

microtiter wells or micelles, each compartment containing a specific template molecule and the templated polyether, in many copies. In this way, the template and templated molecule is physically associated (by the boundaries of the compartment), and therefore the templates encoding polyethers with interesting characteristics may be collected from those compartments, pooled, amplified and "translated" into more copies of polyethers which may then be exposed to a new round of screening.

Figure 20. Zipping-polymerization and activation by rearrangement.

[0139] The initiator is activated for attack by Y. Reaction of initiator and Y results in release of the initiator from the complementing element. Upon reaction with the initiator, a rearrangement of the building block molecule takes place, resulting in activation of X for reaction with Y. After a number of reactions and rearrangements, a polymer has been formed.

Figure 21. Zipping-polymerization and activation by ring opening.

[0140] Reaction of the initiator with X in the ring structure opens the ring, resulting in activation of Y. Y can now react with X in a neighboring functional entity. As a result of ring-opening, the functional entities are released from the complementing elements.

Figure 22. Directional polymer formation using fixed functional units.

[0141]

(A) The functional entity of a building block may be attached to the complementing element through two linkers. This may fix the functional entity in a given orientation relative to the complementing template. As a result, rotation around the linker that connects functional entity and complementing element (as depicted in figure 13) is not possible, and cluster formation therefore unlikely.

(B) Two linkers connect the two bases of a dinucleotide-derivative with the functional unit, which in this case is a dipeptide. Incorporation of such dinucleotide derivatives into a double helical structure will position the amine (X in

(A) above) in proximity to the ester (Y in (A) above). This ester may be activated, for example as a N-hydroxy-succinimide ester. After reaction of the amine and the ester, a polypeptide is formed. This polypeptide will be a directional polymer, with N-to-C-terminal directionality. In the present case, the polymerisation reaction will cleave the ester from the base to which it is linked. Therefore, activation of the formed polymer only requires cleavage of the linker that connects the base at the 3'-end of the dinucleotide with the amino-terminal end of the functional entity.

Rotational fixation of the functional entity relative to the complementing element may be achieved in other ways. For example, the functional entity may be coupled to the complementing element through a double bond, or it may be attached through two bonds to the base and ribose moiety of a nucleotide, respectively, or it may be coupled to different positions on the ribose or base. Finally, it is also possible to link to the phosphate moiety, especially of a dinucleotide.

[0142] Figure 23 shows four examples of bifunctional FEs attached via a single linker to the parent nucleotide (left) or with an additional linker using a second attachment point (right). The second attachment can be anywhere on a neighbour nucleotide (A), on the sugar moiety of the parent nucleotide (B, linked through ester functionality or C, with ester functionality free, and D, also with ester functionality free), it can be another base position of the parent nucleotide (not shown), or the FE could be linked to the phosphate backbone (not shown).

[0143] Figure 24 show a DNA double helix (upper strand 5'-GCTTTT TAG-3') bearing linker-FE 1A attached in different ways. DNA backbones are shown as arrows, sugars and bases as rings. Linker-FE atoms are depicted in stick representation and coloured by atom. A. Example of a conformation bearing singly-attached FEs. B. Most probable product of A. C. Example of a singly-attached FE configuration leading to clustering and thereby to an incomplete product, D. E. Minimum energy conformation bearing doubly-attached FEs and the only possible product, F. G. Stick representation of the released product from F. H. Stick representation of the released product from B. I. Stick representation of the released product from D.

[0144] Figure 25 show a DNA double helix (upper strand 5'-GCTTTT TAG-3') bearing linker-FE 1 B attached in different ways. DNA backbones are shown as arrows, sugars and bases as rings. Linker-FE atoms are depicted in stick representation and coloured by atom. A. Minimum energy conformation bearing singly-attached FEs. B. Most probable product of A. C. Example of a singly-attached FE configuration leading to clustering and thereby to an incomplete product, D. E. Minimum energy conformation bearing doubly-attached FEs and the only possible product, F. G. Stick representation

of the released product from B and F. H. Stick representation of the released product from D.

Figure 26. Templating of molecules - principle and variations.

[0145] In the figures 26-27, 29-31, 33-35, 37-49, and 53, the template, the complementing template, both the template and the complementing template, or a complementing element is indicated by a horizontal (bold) line. In figures 26-28, 35-37, and 39, a circle is used to indicate a functional entity.

A. Monomer building blocks used in this figure. A black dot indicates a cleavable linker.

B. General principle.

Step 1 - Incorporation. The monomer building blocks are specifically incorporated into a complementary template, by specific interaction between coding elements (of the template) and complementing elements (of the monomer building blocks).

Step 2 - Reaction. A reaction is induced by which functional entities (FE) of the individual monomer building blocks become coupled, by reaction of reactive groups type II.

Step 3 - Activation. Some or all of the linkers connecting the FE units with complementing elements are cleaved, thereby partly or fully releasing the templated molecule.

Step 4 (not shown in figure) - Screening, Amplification and Modification.

The template-templated molecule complexes may be taken through a screening process that enriches the pool for complexes with desired features. Then the templates of the enriched pool may be amplified and modified, by e.g. mutagenic PCR, and the templated molecules regenerated by performing step 1-3.

C. Templating of linear, branched and circular templates.

Linear, branched and circular templates may generate linear, branched and circular templated molecules. In the example shown, the branched template may be generated by incorporation of a modified nucleotide (e.g., carrying a thiol) into an oligonucleotide, followed by reaction with an oligonucleotide containing a thiol-reactive component (e.g., a maleimide-unit at one end). The circular template may likewise be a oligonucleotide, carrying reactive groups at the end that may react to covalently close the circle (e.g., thiols at both ends of the oligonucleotide could form an disulfide bond). Upon cleavage of all but one of the linkers connecting the FEs and complementing elements, a circular templated molecule is formed, attached to the template at one point.

D. Templating of linear, branched, circular and scrambled linear molecules by linear template.

(a) A linear templated molecule with the same sequence of FEs as obtained after incorporation, but before reaction, of the monomer building blocks. (b) A linear templated molecule with a scrambled sequence, i.e., the sequence of the FEs in the templated molecule does not correspond to the sequence obtained right after incorporation, but before reaction of the FEs. (c) A circular templated molecule obtained by pairwise reaction of the following FEs with each other: FE1/FE2, FE2/FE3, FE3/FE5, FE5/FE4, FE4/FE1. (d) A branched molecule obtained by pairwise reaction of the following functional entities with each other: FE1/FE2, FE2/FE3, FE2/FE4, and FE4/FE5. (e) A branched molecule obtained by pairwise reaction of the following functional entities with each other: FE1/FE2, FE2/FE4, FE2/FE5, FE2/FE3.

[0146] Figure 27. Non-equal number of reactive groups (X) and (Y). The number of reactive groups (X) can be higher than, equal to, or lower than the number of reactive groups (Y). When the number of (X) and (Y) are different, scrambling results. In the figure the scaffold (the molecular moiety to which the functional groups of the monomer building blocks become attached) is directly attached to the template. The scaffold may also be part of a monomer building block (i.e., the functional entity of the monomer building block comprises a scaffold moiety, including reactive groups type II (Y).

(A). Number of encoded reactive groups X per template equals the number of reactive groups (Y) on the anchorage point (also called the scaffold).

(B). Number of encoded reactive groups X per template is less than the number of encodable substituent positions Y on the scaffold. This leads to scrambling regarding which of the reactive groups (Y) on the scaffold (anchorage point) will react with an (X) on the monomer building blocks.

C. Number of encoded reactive groups X per template is larger than the number of reactive groups on the scaffold. This leads to scrambling regarding which of the reactive groups (Y) on the scaffold (anchorage point) will react with

a reactive group (X) on the monomer building blocks.

Figure 28. Monomer building blocks.

[0147]

(A) A monomer building block with one reactive group type II (X), connecting the functional group (Rx) with the complementing element. This type of monomer building block may be used for the simultaneous reaction and activation protocol (Figure 14).

(B) A monomer building block with two reactive groups type II (X and Y), connecting the complementing element and the functional group (Rx).

(C) A monomer building block with one reactive group type II (X). The reactive group (X) does not link the functional group (Rx) and the complementing element, wherefore a linker (L) is needed for the activation step (in order to release the functional entity from the complementing element)

(D) A monomer building block with four reactive groups type II (Y). The four reactive groups and the functional group Rx may serve as a scaffold, onto which substituents (encoded by monomers complementing the same template) are coupled through reaction of reactive groups (X) on these monomer building blocks with the reactive groups (Y) on this monomer building block. In this example, no cleavable linker is indicated. Therefore, after the templating reactions the templated molecule may be attached to the template through the linker of this monomer building block.

Figure 29. Templating involving simultaneous reaction and activation.

[0148] Templating using 4 monomer building blocks each with one reactive group type II (X), and an anchorage point carrying 4 reactive groups (Y). The reaction of X and Y involves simultaneous activation (cleavage) which releases X from the complementing element.

(A) The reactive groups type II (X) are of similar kind.

(B) The reactive groups type II (X1, X2, X3, X4) are of different kinds, i.e. the pairwise reactions between reactions X1/Y1, X2/Y2, X3/Y3, and X4/Y4 are orthogonal or partly orthogonal. For example, X1 preferably reacts with Y1, not Y2, Y3 or Y4. The anchorage point may be attached directly to the template, or to the complementing template. In case the anchorage point is attached to a complementing element, as a whole it is considered a monomer building block.

Figure 30. Reaction types allowing simultaneous reaction and activation.

[0149] Different classes of reactions are shown which mediate translocation of a functional group from one monomer building block to another, or to an anchorage point. The reactions have been grouped into three different classes: Nucleophilic substitutions, addition-elimination reactions, and transition metal catalyzed reactions. These reactions are compatible with simultaneous reaction and activation (as described in general terms in figure 14).

(A) Reaction of nucleophiles with carbonyls. As a result of the nucleophilic substitution, the functional group R is translocated to the monomer building block initially carrying the nucleophile.

(B) Nucleophilic attack by the amine on the thioester leads to formation of an amide bond, in effect translocating the functional group R of the thioester to the other monomer building block.

(C) Reaction between hydrazine and β -ketoester leads to formation of pyrazolone, in effect translocating the R and R' functional groups to the other monomer building block.

(D) Reaction of hydroxylamine with β -ketoester leads to formation of the isoxazolone, thereby translocating the R and R' groups to the other monomer building block.

(E) Reaction of thiourea with p-ketoester leads to formation of the pyrimidine, thereby translocating the R and R' groups to the other monomer building block.

(F) Reaction of urea with malonate leads to formation of pyrimidine, thereby translocating the R group to the other monomer building block.

(G) Depending on whether Z = O or Z = NH, a Heck reaction followed by a nucleophilic substitution leads to formation of coumarin or quinolinon, thereby translocating the R and R' groups to the other monomer building block.

(H) Reaction of hydrazine and phthalimides leads to formation of phthalhydrazide, thereby translocating the R and R' groups to the other monomer building block.

(I) Reaction of amino acid esters leads to formation of diketopiperazine, thereby translocating the R group to the other monomer building block.

(J) Reaction of urea with α -substituted esters leads to formation of hydantoin, and translocation of the R and R' groups to the other monomer building block.

(K) Alkylation may be achieved by reaction of various nucleophiles with sulfonates. This translocates the functional groups R and R' to the other monomer building block.

(L) Reaction of a di-activated alkene containing an electron withdrawing and a leaving group, whereby the alkene is translocated to the nucleophile.

(M) Reaction of disulfide with mercaptane leads to formation of a disulfide, thereby translocating the R' group to the other monomer building block.

(N) Reaction of amino acid esters and amino ketones leads to formation of benzodiazepinone, thereby translocating the R group to the other monomer building block.

(O) Reaction of phosphonates with aldehydes or ketones leads to formation of substituted alkenes, thereby translocating the R" group to the other monomer building block.

(P) Reaction of boronates with aryls or heteroaryl results in transfer of an aryl group to the other monomer building block (to form a biaryl).

(Q) Reaction arylsulfonates with boronates leads to transfer of the aryl group.

(R) Reaction of boronates with vinyls (or alkynes) results in transfer of an aryl group to the other monomer building block to form a vinylarene (or alkynylarene).

(S) Reaction between aliphatic boronates and arylhalides, whereby the alkyl group is translocated to yield an alkylarene.

(T) Transition metal catalysed alpha-alkylation through reaction between an enolether and an arylhalide, thereby translocating the aliphatic part.

(U) Condensations between e.g. enamines or enolethers with aldehydes leading to formation of alpha-hydroxy carbonyls or alpha,beta-unsaturated carbonyls. The reaction translocates the nucleophilic part.

(V) Alkylation of alkylhalides by e.g. enamines or enolethers. The reaction translocates the nucleophilic part.

(W) [2+4] cycloadditions, translocating the diene-part.

(X) [2+4] cycloadditions, translocating the ene-part.

(Y) [3+2] cycloadditions between azides and alkenes, leading to triazoles by translocation of the ene-part.

(Z) [3+2] cycloadditions between nitriloxides and alkenes, leading to isoxazoles by translocation of the ene-part.

Figure 31. Templating involving non-simultaneous reaction and activation: Reaction of reactive groups (type II), followed by cleavage of the linkers that connect functional entities with complementing elements.

[0150] Templating using 4 monomer building blocks each with one reactive group type II (X), and an anchorage point carrying 4 reactive groups (Y). The reaction of X and Y does not involve simultaneous activation (cleavage), wherefore the reaction of X and Y is followed by cleavage of the linker L, which releases the functional group Rx from the complementing element.

(A) The reactive groups type II (X) are of similar kind, i.e., they may react with the same type of reactive group (Y).

(B) The reactive groups type II (X1, X2, X3, X4) are of different kinds, i.e. the reactions between X1/Y1, X2/Y2, X3/Y3, and X4/Y4 are orthogonal or partly orthogonal. For example, X1 preferably reacts with Y1, not Y2, Y3 or Y4. The anchorage point may be attached directly to the template, or to the complementing template. In case the anchorage point is attached to a complementing element, as a whole it is considered a monomer building block.

Figure 32. Pairs of reactive groups (X) and (Y), and the resulting bond (XY).

[0151] A collection of reactive groups that may be used for templated synthesis are shown, along with the bonds formed upon their reaction. After reaction, activation (cleavage) may be required (see Figure 31).

Figure 33. Anchorage sites for the templated molecule.

[0152] The templated molecule may be attached to the template that encodes it (A) through a linker that is connected directly to the template near the end of the template, or (B) through a linker that is connected directly to the template, at a more central position on the template, or (C) by way of a monomer building block carrying the anchorage point (a reactive group that becomes the linkage to the templated molecule).

Figure 34. Scrambling.

[0153] When the functional entities react after incorporation of the monomer building blocks, the position or sequence

of functional groups in the templated molecule may not always be uniquely determined by the template sequence.

- (1) The functional groups R1, R2, R3, and R4 may take any of the four positions on the scaffold molecule (i.e., the reactive group X of a monomer building block may react with any of the reactive groups Y on the anchorage point.
- (2) The sequence of one arm of this branched molecule may be e.g. R5-R3-R2 (as shown), or R5-R2-R3 (not shown), or R5-R4-R3 (not shown), or any other of a number of possible sequences. Also, the identity of the functional group coupled to e.g. the left part of the molecule, may be either of any of R1, R2, R3, or R4.
- (3) As in (2), a number of possible sequences of functional groups are possible, in addition to the shown sequence R1-R2-R5-R4-R3.
- (4) Here a non-scrambled templated molecule is shown, in which the sequence of the functional entities when incorporated corresponds to the sequence of the templated molecule (R1-R2-R3-R4-R5). When desired, scrambling may be partly or fully avoided by directional encoding or the use of for example zipper boxes in the linkers (see figures 40, 44-47).
- (5) As in (2) and (3), a number of possible sequences and positions of the functional entities are possible.

Figure 35. Monomer building blocks - examples of linker design.

[0154] Different designs of monomer building blocks are shown, used in various schemes of templating.

The complementing element may be represented by an oligonucleotide, to which a linker carrying the functional entity is attached. The linker may occupy an internal position with respect to the complementing element or alternatively occupy a terminal position. Both the complementing element and the linker may be made up of an oligonucleotide (DNA, RNA, LNA, PNA, other oligomers capable of hybridizing to the linker of a monomer building block and mixtures thereof). The horizontal part represents the complementing element, and the vertical part represents the linker.

The portion of the linker marked "a" may be present or absent. Region "a" represents an interaction region of which one preferred embodiment is a sequence of nucleotides. Region "a" may be annealed to a complementary single stranded nucleotide sequence "a'" in order to make the linker more rigid. Alternatively region "a" may be used for interaction with other monomer building blocks (i.e. zipper box see fig. 42), whereby the functional entities of such two monomer building blocks will be brought in close proximity, which will increase probability of reaction between these two functional entities. Other uses of such regions includes interaction between different monomer building blocks whereby directional encoding may be achieved. "Nu" is a nucleophile that may react with an electrophile "E".

Different designs of monomer building blocks are shown, used in various schemes of templating.

(A) The complementing element may be an oligonucleotide, to which a linker carrying the functional entity is attached to the central part of the oligonucleotide. The portion of the linker marked "a" may represent a nucleotide sequence to which a single stranded nucleotide may be annealed in order to make the linker more rigid.

(B) Both the complementing element and the linker may be made up of an oligonucleotide. The horizontal part here represents the complementing element, and the vertical part represents the linker. The linker may contain a sequence "a" that functions as a zipper box (see figure 42).

(C) The monomer building blocks of (C) is an initiator or anchorage point which may be used to initiate the encoding process.

Figure 36 Preparation of functional entities to oligonucleotide-based monomer building blocks.

[0155] Reactions and reagents are shown that may be used for the coupling of functional entities to modified oligonucleotides (modified with thiol, carboxylic acid, halide, or amine), without significant reaction with the unmodified part of the oligonucleotide or alternatively, connective reactions for linkage of linkers to complementing elements. Commercially, mononucleotides are available for the production of starting oligonucleotides with the modifications mentioned.

Figure 37 Oligonucleotide-based monomer building blocks. Examples of linker and functional entity (FE) design and synthesis.

[0156] Examples are shown where the complementing elements of the monomer building blocks comprises oligonucleotides of length e.g. 8-20 nucleotides (oligonucleotide is drawn as a thick black line). Part of or all of the oligonucleotide may comprise the complementing element. In the case where only part of the oligonucleotide represents the complementing element, the remaining portion of the oligonucleotide may constitute a linker. In the examples, a linker is attached to the base on the 3'- or 5'-end of the oligonucleotide. This linker may be attached on any nucleotide in the oligonucleotide sequence, and also, it may be attached to any molecular moiety on the oligonucleotide, as long as it does not abolish specific interaction of the complementing element with the template.

(A) A monomer building block in which the linker (L) connects the base of the terminal nucleotide with the functional entity.

(B) A monomer building block in which a polyethylene glycol (PEG) linker of between one and twenty ethylene glycol units connects the complementing element with the functional entity which contains a nucleophile (a primary amine).

(C) A monomer building block in which a linker (L) connects the functional entity which contains an electrophile (an ester or thioester).

(D) A monomer building block comprising a Boc-protected amine (which may be deprotected with mild acid), and an ester. The deprotected amine may react with an ester of another monomer building block, to give an amide bond.

Figure 38. Oligonucleotide-based monomer building blocks. Example of coding and complementing element design, allowing for high monomer diversity.

[0157]

(A) Template carrying 6 coding elements (BOX 1-6), each containing a partly random sequence (X specifies either C or G), and a constant sequence that is identical for all sequences in the group (e.g., all BOX 1 sequences carry a central ATATTT sequence). By using C and G only (or, alternatively, A and T only), the individual sequences (e.g., the sequences belonging to the group of BOX 1 sequences), have almost identical annealing temperatures wherefore mis-annealing is insignificant. In the example, BOX 2 and BOX 3 are identical wherefore BOX 2 and BOX 3 may encode the same type of functional entities (comprising the same type of reactive groups of type II). The attachment point of the linker that connects the complementing element and the functional entity is not specified in the figure. Ideally, the linker is attached to a nucleotide in the constant region, in order to avoid bias in the annealing process.

(B) Example of coding element sequences. Example BOX 1 and BOX 6 sequences are shown. The example BOX 1 sequence represents one specific sequence out of 1024 different sequences that anneal specifically to the corresponding BOX 1 complementing elements; the example BOX 6 sequence represents one specific sequence out of 128 different sequences that anneal to the corresponding BOX 6 complementing elements.

(C) Templating using six monomers. Five classes of coding elements are used (BOX 2 and 3 are of the same class, i.e., the corresponding complementing elements of this class may anneal to both BOX 2 and 3). Reactive groups type II X and Y react; S and T react; A and B react; and C and D react. In the example the X/Y pair is orthogonal to S/T orthogonal to A/B orthogonal to C/D. Reaction of X with Y results in cleavage of R1 from the complementing element and translocation to R4. Reaction of S and T, followed by cleavage of the linker L leads to translocation of R2 and R3 onto R4. Reaction of A with B, and C with D translocates R5 and R6 to R4. In this example, the functional entity of the monomer binding to BOX 4 serves as a "scaffold" onto which is added various substituents.

Figure 39: A typically panning protocol for selection of templated molecules

[0158] Templates presenting the various small molecule variants are produced by DNA encoding technology. These templated molecules are incubated with the immobilized target molecule. Templated molecules with low affinity for the target are washed away. The remaining templated molecules are eluted and the template is amplified using PCR. The enriched templates are then ready to be used as a coding strand for the next cycle.

Figure 40: Array of templated molecules

[0159] The figure shows a templated molecule chip. A DNA library is spotted in array format on a suitable surface. The templated molecule library (single-stranded template DNA) is added and allows hybridizing to the complement DNA strand. This will allow site-specific immobilization of the templated molecules. A biological sample containing target molecules is added and non-bound material is washed off. The final step is the detection of bound material in each single spot.

Figure 41. Use of rigid or partially rigid linkers to increase probability of reaction between the functional entities of the incorporated monomer building blocks.

[0160]

(A) By using linkers comprising one or more flexible regions ("hinges") and one or more rigid regions, the probability of two functional entities getting into reactive contact may be increased.

(B) Symbol used for monomer building block with a rigid part and two flexible hinges.

(C) A monomer building block with the characteristics described in (B): The monomer building block contains an

oligonucleotide as complementing element (horizontal line), and a oligonucleotide as linker connecting the functional entity (FE) with the complementing element. Annealing of a complementary sequence to the central part of the linker leads to formation of a rigid double helix; at either end of the linker a single-stranded region remains, which constitutes the two flexible hinges.

Figure 42. Use of zipper box to increase probability of reaction between the functional entities of the incorporated monomer building blocks.

[0161]

(A) The linkers in this example carry zipper boxes (a) or (a'), that are complementary. By operating at a temperature that allows transient interaction of (a) and (a'), the reactive groups X and Y are brought into close proximity during multiple annealing events, which has the effect of keeping X and Y in close proximity in a larger fraction of the time than otherwise achievable. Alternatively, one may cycle the temperature between a low temperature (where the zipper boxes pairwise interacts stably), and a higher temperature (where the zipper boxes are apart, but where the complementing element remains stably attached to the coding element of the template). By cycling between the high and low temperature several times, a given reactive group X is exposed to several reactive groups Y, and eventually will react to form an XY bond.

(B) Sequences of two oligonucleotide-based monomer building blocks. The region constituting the complementing element, linker and zipper box is indicated.

Figure 43. Templated synthesis of organic compounds - examples.

[0162]

(A) Three monomer building blocks are used. Each monomer building block comprises an activated ester (reactive group of type II, (X)) where the ester moiety carries a functional group Rx. Upon reaction between the esters and the amines on the scaffold (scaffold may be attached to the template), amide bonds are formed, and the Rx groups are now coupled to the scaffold via amide bonds. This is thus an example of simultaneous reaction (amide formation) and activation (release of the Rx moiety from the complementing elements), see figure 29.

(B) Analogously to (A), three amines react with three esters to form three amide bonds, thereby coupling the functional groups Rx to the scaffold moiety. However, as opposed to (A), the scaffold is here encoded by the template.

(C) Three monomer building blocks are used. The nucleophilic amine at the far right (part of the anchorage point) attacks the ester carbonyl of the third monomer; the amine of the third monomer attacks the thioester of the second monomer, and the Horner-Wittig Emmans reagent of the first monomer reacts with the aldehyde of the third monomer under alkaline conditions. This forms the templated molecule. The double bond may be post-templating modified by hydrogenation to form a saturated bond, or alternatively, subjected to a Michael addition.

(D) The thiol of the scaffold reacts with the pyridine-disulfide of monomer 1. The amine of the scaffold reacts with the ester of the second monomer. The double nitril activated alpha-position is acylated by the monomer 3's thioester in the presence of base. The aryl iodide undergoes Suzuki coupling with the arylboronate of monomer 4 to yield the biaryl moiety.

(E) Monomer 1 acylates the primary amine. The aryl iodide undergoes a Suzuki coupling by monomer 2 and the benzylic amine is acylated by monomer 3.

Acylation of the hydrazine followed by cyclization leads to formation of an hydroxypyrazole. The arylbromide undergoes Suzuki coupling with the aryl boronate of monomer 1 and finally the aldehyde reactions with the Horner-Wittig-Emmons reagent of monomer 4 to yield an alpha, beta-unsaturated amide, which may be further functionalized by either reduction with H₂/Pd-C or undergo Michael addition with nucleophiles.

Figure 44. α - and β -peptides, hydrazino peptides and peptoids. Encoding by use of oligonucleotide-based monomer building blocks.

[0163] It is shown how templated synthesis may be used to generate α - and β -peptides, hydrazino peptides and peptoids.

Figure 45. Templating of α -, p-, γ -, and ω -peptide through use of cyclic anhydrides

[0164] It is shown how templated synthesis may be used to generate α -, β -, γ - and ω -peptides, through the use of

cyclic anhydrides.

Figure 46. Generation of new reactive groups upon reaction of the reactive groups X and Y.

[0165] In cases where the reaction of X and Y leads to formation of a new reactive group Z, this may be exploited to increase the diversity of the templated molecule, by incorporating monomer building blocks carrying reactive groups Q that react with Z.

(A) X and Y react to form Z, which in itself does lead to release from the complementing element. Upon reaction of Z with Q, and cleavage of the linker that connects Z to the complementing element, the templated molecule is formed.

(B) In this case, reaction of X and Y to form Z simultaneously cleaves the linker connecting X to the complementing element. Upon reaction of Z with Q, the templated molecule is formed.

Figure 46, example 1. Templated synthesis by generating a new reactive group.

[0166] The reaction of the functional entities of the first three monomer building blocks leads to formation of two double bonds, which may react with two hydroxylamines carried in by the monomer building blocks added in the second step, and leads to formation of an ester, which may react with the an hydroxylamine, carried in by the monomer added in the second step. Finally, the linkers are cleaved, generating the templated molecule.

Figure 47. Cleavable linkers.

[0167] Cleavable linkers, the conditions for their cleavage, and the resulting products are shown.

Figure 48. Post-templating modification of templated molecule.

[0168] After the templating process has been performed, the templated molecules may be modified to introduce new characteristics. This list describes some of these post-templating modifications.

Definitions

[0169] α -peptide: Peptide comprising or essentially consisting of at least two α -amino acids linked to one another by a linker including a peptide bond.

[0170] Amino acid: Entity comprising an amino terminal part (NH_2) and a carboxy terminal part (COOH) separated by a central part comprising a carbon atom, or a chain of carbon atoms, comprising at least one side chain or functional group. NH_2 refers to the amino group present at the amino terminal end of an amino acid or peptide, and COOH refers to the carboxy group present at the carboxy terminal end of an amino acid or peptide. The generic term amino acid comprises both natural and non-natural amino acids. Natural amino acids of standard nomenclature as listed in J. Biol. Chem., 243:3552-59 (1969) and adopted in 37 C.F.R., section 1.822(b)(2) belong to the group of amino acids listed in Table 2 herein below. Non-natural amino acids are those not listed in Table 2. Examples of non-natural amino acids are those listed e.g. in 37 C.F.R. section 1.822(b)(4), all of which are incorporated herein by reference. Further examples of non-natural amino acids are listed herein below. Amino acid residues described herein can be in the "D" or "L" isomeric form.

Table 2. Natural amino acids and their respective codes.

	Symbols		Amino acid
	1-Letter	3-Letter	
	Y	Tyr	tyrosine
	G	Gly	glycine
	F	Phe	phenylalanine
	M	Met	methionine
	A	Ala	alanine
	S	Ser	serine
	I	Ile	isoleucine
	L	Leu	leucine
	T	Thr	threonine
	V	Val	valine
	P	Pro	proline
	K	Lys	lysine
	H	His	histidine
	Q	Gln	glutamine
	E	Glu	glutamic acid
	W	Trp	tryptophan
	R	Arg	arginine
	D	Asp	aspartic acid
	N	Asn	asparagine
	C	Cys	cysteine

[0171] Amino acid precursor: Moiety capable of generating an amino acid residue following incorporation of the precursor into a peptide.

[0172] Amplifying: Any process or combination of process steps that increases the number of copies of a templated molecule. Amplification of templated molecules may be carried out by any state of the art method including, but not limited to, a polymerase chain reaction to increase the copy number of each template, and using the templates for synthesising additional copies of the templated molecules comprising a sequence of functional groups resulting from the synthesis of the templated molecule being templated by the template. Any amplification reaction or combination of such reactions known in the art can be used as appropriate as readily recognized by those skilled in the art. Accordingly, templated molecules can be amplified by using the polymerase chain reaction (PCR), ligase chain reaction (LCR), in vivo amplification of cloned DNA, and the like. The amplification method should preferably result in the proportions of the amplified mixture being essentially representative of the proportions of templates of different sequences in a mixture prior to amplification.

[0173] Base: Nitrogenous base moiety of a natural or non-natural nucleotide, or a derivative of such a nucleotide

comprising alternative sugar or phosphate moieties. Base moieties include any moiety that is different from a naturally occurring moiety and capable of complementing one or more bases of the opposite nucleotide strand of a double helix.

[0174] Building block: Species comprising a) at least one complementing element comprising at least one recognition group capable of recognising a predetermined coding element, b) at least one functional entity comprising a functional group and a reactive group, and c) at least one linker separating the at least one functional entity from the at least one complementing element, wherein the building block does not comprise a ribosome. Preferred building blocks are capable of being incorporated into a nucleotide strand and/or capable of being linked by reactions involving reactive groups of type I and/or type II as described herein.

[0175] Cleavable linker: Residue or bond capable of being cleaved under predetermined conditions.

[0176] Cleaving: Breaking a chemical bond. The bond may be a covalent bond or a non-covalent bond.

[0177] Coding element: Element of a template comprising a recognition group and capable of recognising a predetermined complementing element of a building block. The recognition may result from the formation of a covalent bond or from the formation of a non-covalent bond between corresponding pairs of coding elements and complementing elements capable of interacting with one another.

[0178] Coding element complementation: Contacting a coding element with a predetermined complementing element capable of recognising said coding element.

[0179] Complementing: Process of bringing a coding element into reactive contact with a predetermined complementing element capable of recognising said coding element. When the coding element and the complement element comprises a natural nucleotide comprising a base moiety, predetermined sets of nucleotides are capable of complementing each other by means of hydrogen bonds formed between the base moieties.

[0180] Complementing element: Element of a building block. Linked to at least one functional entity by means of a linker. See coding element.

[0181] Complementing template: A sequence of complementing elements, wherein each complementing element is covalently linked to a neighbouring complementing element. A complementing element is capable of recognising a predetermined coding element. The complementing template may be linear or branched.

[0182] Complex: Templated molecule linked to the template that templated the synthesis of the templated molecule. The template can be a complementing template as defined herein that is optionally hybridised or otherwise attached to a corresponding template of linked coding elements.

[0183] Contacting: Bringing e.g. corresponding reactive groups or corresponding binding partners or hybridization partners into reactive contact with each other. The reactive contact is evident from a reaction or the formation of a bond or a hybridization between the partners.

[0184] Corresponding binding partners: Binding partners capable of reacting with each other.

[0185] Corresponding reactive groups: Reactive groups capable of reacting with each other.

[0186] Functional entity: Entity forming part of a building block. The functional entity comprises a functional group and a reactive group capable of linking neighbouring, functional groups.

[0187] Functional group: Group forming part of a templated molecule. The sequence of functional groups in a templated molecule is a result of the capability of the template to template the synthesis of the templated molecule.

[0188] Interacting: Used interchangeably with contacting. Bringing species such as e.g. corresponding binding partners in the form of e.g. coding elements and complementing elements into reactive contact with each other. The reaction may be mediated by recognition groups forming corresponding binding partners by means of covalent or non-covalent bonds. The interaction may occur as a result of mixing a template comprising a plurality of coding elements with a plurality of building blocks.

[0189] Ligand: Used herein to describe a templated molecule capable of targeting a target molecule. In a population of candidate template molecules, a ligand is one which binds with greater affinity than that of the bulk population. In a candidate mixture there can exist more than one ligand for a given target. The ligands can differ from one another in their binding affinities for the target molecule.

[0190] Linker: A residue or chemical bond separating at least two species. The species may be retained at an essentially fixed distance, or the linker may be flexible and allow the species some freedom of movement in relation to each other. The link can be a covalent bond or a non-covalent bond. Linked species include e.g. a complementing element and a functional entity of a building block, neighbouring coding elements of a template, neighbouring complementing elements of a complementing template, and neighbouring functional groups of a templated molecule.

[0191] Natural nucleotide: Any of the four deoxyribonucleotides, dA, dG, dT, and dC (constituents of DNA), and the four ribonucleotides, A, G, U, and C (constituents of RNA) are the natural nucleotides. Each natural nucleotide comprises or essentially consists of a sugar moiety (ribose or deoxyribose), a phosphate moiety, and a natural/standard base moiety. Natural nucleotides bind to complementary nucleotides according to well-known rules of base pairing (Watson and Crick), where adenine (A) pairs with thymine (T) or uracil (U); and where guanine (G) pairs with cytosine (C), wherein corresponding base-pairs are part of complementary, anti-parallel nucleotide strands. The base pairing results in a specific hybridization between predetermined and complementary nucleotides. The base pairing is the basis by which

enzymes are able to catalyze the synthesis of an oligonucleotide complementary to the template oligonucleotide. In this synthesis, building blocks (normally the triphosphates of ribo or deoxyribo derivatives of A, T, U, C, or G) are directed by a template oligonucleotide to form a complementary oligonucleotide with the correct, complementary sequence. The recognition of an oligonucleotide sequence by its complementary sequence is mediated by corresponding and interacting bases forming base pairs. In nature, the specific interactions leading to base pairing are governed by the size of the bases and the pattern of hydrogen bond donors and acceptors of the bases. A large purine base (A or G) pairs with a small pyrimidine base (T, U or C). Additionally, base pair recognition between bases is influenced by hydrogen bonds formed between the bases. In the geometry of the Watson-Crick base pair, a six membered ring (a pyrimidine in natural oligonucleotides) is juxtaposed to a ring system composed of a fused, six membered ring and a five membered ring (a purine in natural oligonucleotides), with a middle hydrogen bond linking two ring atoms, and hydrogen bonds on either side joining functional groups appended to each of the rings, with donor groups paired with acceptor groups.

[0192] Neighbouring: Elements, groups, entities or residues located next to one another in a sequence are said to be neighbouring. In cases where two complementing elements, each linked to a functional entity, are linked to one another through one (or more) complementing element(s) that is not linked to a functional entity, the aforementioned complementing elements are said to be neighbouring and said two complementing elements define neighbouring functional entities and neighbouring coding elements that can be linked to one another, either directly or through one (or more) coding element(s).

[0193] Non-natural amino acid: Any amino acid not included in Table 2 herein above. Non-natural amino acids includes, but is not limited to modified amino acids, L-amino acids, and stereoisomers of D-amino acids.

[0194] Non-natural base pairing: Base pairing among non-natural nucleotides, or among a natural nucleotide and a non-natural nucleotide. Examples are described in US 6,037,120, wherein eight non-standard nucleotides are described, and wherein the natural base has been replaced by a non-natural base. As is the case for natural nucleotides, the non-natural base pairs involve a monocyclic, six membered ring pairing with a fused, bicyclic heterocyclic ring system composed of a five member ring fused with a six membered ring. However, the patterns of hydrogen bonds through which the base pairing is established are different from those found in the natural AT, AU and GC base pairs. In this expanded set of base pairs obeying the Watson-Crick hydrogen-bonding rules, A pairs with T (or U), G pairs with C, iso-C pairs with iso-G, and K pairs with X, H pairs with J, and M pairs with N (Figure 2). Nucleobases capable of base pairing without obeying Watson-Crick hydrogen-bonding rules have also been described (Berger et al., 2000, *Nucleic Acids Research*, 28, pp. 2911-2914).

[0195] Non-natural nucleotide: Any nucleotide not falling within the definition of a natural nucleotide.

[0196] Nucleotide: Nucleotides as used herein refers to both natural nucleotides and non-natural nucleotides capable of being incorporated - in a template-directed manner - into an oligonucleotide, preferably by means of an enzyme comprising DNA or RNA dependent DNA or RNA polymerase activity, including variants and functional equivalents of natural or recombinant DNA or RNA polymerases. Corresponding binding partners in the form of coding elements and complementing elements comprising a nucleotide part are capable of interacting with each other by means of hydrogen bonds. The interaction is generally termed "base-pairing". Nucleotides may differ from natural nucleotides by having a different phosphate moiety, sugar moiety and/or base moiety. Nucleotides may accordingly be bound to their respective neighbour(s) in a template or a complementing template by a natural bond in the form of a phosphodiester bond, or in the form of a non-natural bond, such as e.g. a peptide bond as in the case of PNA (peptide nucleic acids).

[0197] Nucleotide analog: Nucleotide capable of base-pairing with another nucleotide, but incapable of being incorporated enzymatically into a template or a complementary template. Nucleotide analogs often includes monomers or oligomers containing non-natural bases or non-natural backbone structures that do not facilitate incorporation into an oligonucleotide in a template-directed manner. However, interaction with other monomers and/or oligomers through specific base pairing is possible. Alternative oligomers capable of specifically base pairing, but unable to serve as a substrate of enzymes, such as DNA polymerases and RNA polymerases, or mutants or functional equivalents thereof, are defined as nucleotide analogs herein. Oligonucleotide analogs includes e.g. nucleotides in which the phosphodiester-sugar backbone of natural oligonucleotides has been replaced with an alternative backbone include peptide nucleic acid (PNA), locked nucleic acid (LNA), and morpholinos.

[0198] Nucleotide derivative: Nucleotide or nucleotide analog further comprising an appended molecular entity. Often, derivatized building blocks (nucleotides to which a molecular entity have been appended) can be enzymatically incorporated into oligonucleotides by RNA or DNA polymerases, using as substrate the triphosphate of the derivatized nucleoside. In many cases such derivatized nucleotides are incorporated into the growing oligonucleotide chain with high specificity, meaning that the derivative is inserted opposite a predetermined nucleotide in the template. Such an incorporation will be understood to be a specific incorporation. The nucleotides can be derivatized on the bases, the ribose/deoxyribose unit, or on the phosphate. Preferred sites of derivatization on the bases include the 8-position of adenine, the 5-position of uracil, the 5- or 6-position of cytosine, and the 7-position of guanine. The nucleotide-analogs described below may be derivatized at the corresponding positions (Benner, United States Patent 6,037,120). Other sites of derivatization may be used, as long as the derivatization does not disrupt base pairing specificity. Preferred sites of derivatization on the ribose

or deoxyribose moieties are the 5', 4' or 2' positions. In certain cases it may be desirable to stabilize the nucleic acids towards degradation, and it may be advantageous to use 2'-modified nucleotides (US patent 5,958,691). Again, other sites may be employed, as long as the base pairing specificity is not disrupted. Finally, the phosphates may be derivatized. Preferred derivatizations are phosphorothioate. Nucleotide analogs (as described below) may be derivatized similarly to nucleotides. It is clear that the various types of modifications mentioned herein above, including i) derivatization and ii) substitution of the natural bases or natural backbone structures with non-natural bases and alternative, non-natural backbone structures, respectively, can be applied once or more than once within the same molecule.

[0199] Oligonucleotide: Used herein interchangeably with polynucleotide. The term oligonucleotide comprises oligonucleotides of both natural and/or non-natural nucleotides, including any combination thereof. The natural and/or non-natural nucleotides may be linked by natural phosphodiester bonds or by non-natural bonds. Oligonucleotide is used interchangeably with polynucleotide.

[0200] Oligomer: Molecule comprising a plurality of monomers that may be identical, of the same type, or different. Oligomer is used synonymously with polymer in order to describe any molecule comprising more than two monomers. Oligomers may be homooligomers comprising a plurality of identical monomers, oligomers comprising different monomers of the same type, or heterooligomers comprising different types of monomers, wherein each type of monomer may be identical or different.

[0201] Partitioning: Process whereby templated molecules, or complexes comprising such molecules linked to a template, are preferentially bound to a target molecule and separated from templated molecules, or complexes comprising such molecules linked to a template, that do not have an affinity for - and is consequently not bound to - such target molecules. Partitioning can be accomplished by various methods known in the art. The only requirement is a means for separating targeted, templated molecules bound to a target molecule from templated molecules not bound to target molecules. The choice of partitioning method will depend on properties of the target molecule and of the templated molecule and can be made according to principles and properties known to those of ordinary skill in the art.

[0202] Peptide: Plurality of covalently linked amino acid residues defining a sequence and linked by amide bonds. The term is used analogously with oligopeptide and polypeptide. The amino acids may be both natural amino acids and non-natural amino acids, including any combination thereof. The natural and/or non-natural amino acids may be linked by peptide bonds or by non-peptide bonds. The term peptide also embraces post-translational modifications introduced by chemical or enzyme-catalyzed reactions, as are known in the art. Such post-translational modifications can be introduced prior to partitioning, if desired. Amino acids as specified herein will preferentially be in the L-stereoisomeric form. Amino acid analogs can be employed instead of the 20 naturally-occurring amino acids. Several such analogs are known, including fluorophenylalanine, norleucine, azetidine-2-carboxylic acid, S-aminoethyl cysteine, 4-methyl tryptophan and the like.

Plurality: At least two.

[0203] Polymer: Templated molecule characterised by a sequence of covalently linked residues each comprising a functional group, including H. Polymers according to the invention comprise at least two residues.

Polynucleotide: See oligonucleotide,

[0204] Precursor: Moiety comprising a residue and being capable of undergoing a reaction during template directed synthesis of a templated molecule, wherein the residue part of the precursor is built into the templated molecule.

[0205] Reactive group: Corresponding reactive groups being brought into reactive contact with each other are capable of forming a chemical bond linking e.g. a coding element and its complementing element, or coupling functional groups of a templated molecule.

[0206] Recognition group: Part of a coding element and involved in the recognition of the complementing element capable of recognising the coding element. Preferred recognition groups are natural and non-natural nitrogenous bases of a natural or non-natural nucleotide.

[0207] Recombine: A recombination process recombines two or more sequences by a process, the product of which is a sequence comprising sequences from each of the two or more sequences. When involving nucleotides, the recombination involves an exchange of nucleotide sequences between two or more nucleotide molecules at sites of identical nucleotide sequences, or at sites of nucleotide sequences that are not identical, in which case the recombination can occur randomly. One type of recombination among nucleotide sequences is referred to in the art as gene shuffling.

[0208] Repetitive sequence: Sequence of at least two elements, groups, or residues, occurring more than once in a molecule.

[0209] Residue: A polymer comprises a sequence of covalently linked residues, wherein each residue comprises a functional group.

[0210] Ribose derivative: Ribose moiety forming part of a nucleoside capable of being enzymatically incorporated into a template or complementing template. Examples include e.g. derivatives distinguishing the ribose derivative from the

ribose of natural ribonucleosides, including adenosine (A), guanosine (G), uridine (U) and cytidine (C). Further examples of ribose derivatives are described in e.g. US 5,786,461. The term covers derivatives of deoxyriboses, and analogously with the above-mentioned disclosure, derivatives in this case distinguishes the deoxyribose derivative from the deoxyriboses of natural deoxyribonucleosides, including deoxyadenosine (dA), deoxyguanosine (dG), deoxythymidine (dT) and deoxycytidine (dC).

[0211] Selectively cleavable linker: Selectively cleavable linkers are not cleavable under conditions wherein a cleavable linker is cleaved. Accordingly, it is possible to cleave the cleavable linkers linking complementing elements and functional groups in a templated molecule without at the same time cleaving selectively cleavable linkers linking - in the same templated molecule - a subset of complementing elements and functional groups. It is thus possible to obtain a complex comprising a templated molecule and the template that has directed the template-mediated synthesis of the templated molecule, wherein the template and the templated molecule are linked by one or more, preferably one, selectively cleavable linker(s).

[0212] Specific recognition: The interaction of e.g. a coding element with preferably one predetermined complementing element. A specific recognition occurs when the affinity of a coding element recognition group for a complementing group results in the formation of predominantly only one type of corresponding binding partners. Simple mis-match incorporation does not exclude a specific recognition of corresponding binding partners. Specific recognition is a term which is defined on a case-by-case basis. In the context of a given interaction between predetermined binding partners, e.g. a templated molecule and a target molecule, a binding interaction of templated molecule and target molecule of a higher affinity than that measured between the target molecule and a candidate template molecule mixture is observed. In order to compare binding affinities, the conditions of both binding reactions must be essentially similar and preferably the same, and the conditions should be comparable to the conditions of the intended use. For the most accurate comparisons, measurements will be made that reflect the interaction between templated molecule as a whole and target as a whole. The templated molecules of the invention can be selected to be as specific as required, either by establishing selection conditions that demand a requisite specificity, or by tailoring and modifying the templated molecules.

[0213] Subunit: Monomer of coding element comprising at least one such subunit.

[0214] Support: Solid or semi-solid member to which e.g. coding elements can be attached during interaction with at least one complementing element of a building block. Functional molecules or target molecules may also be attached to a solid support during targeting. Examples of supports includes planar surfaces including silicon wafers as well as beads.

[0215] Tag: Entity capable of identifying a compound to which it is associated.

[0216] Target molecule: Any compound of interest for which a templated molecule in the form of a ligand is desired. A target molecule can be a protein, fusion protein, peptide, enzyme, nucleic acid, nucleic acid binding protein, carbohydrate, polysaccharide, glycoprotein, hormone, receptor, receptor ligand, cell membrane component, antigen, antibody, virus, virus component, substrate, metabolite, transition state analog, cofactor, inhibitor, drug, controlled substance, dye, nutrient, growth factor, toxin, lipid, glycolipid, etc., without limitation.

[0217] Template: Template refers to both a template of coding elements and a (complementing) template of complementing elements unless otherwise specified. When referring to a template of coding elements, each coding element is covalently linked to a neighbouring coding element. Each coding element is capable of recognising a predetermined complementing element. The template may be linear or branched. A template of coding elements actively takes part in the synthesis of the templated molecule, and the templating activity involves the formation of specific pairing partners in the form of coding element:complementing element hybrids, wherein the complementing element forms part of a building block also comprising the functional group forming part of the templated molecule. The template is preferably a string of nucleotides or nucleotide analogs. When the template comprises a string of nucleotides, the nucleotides may be natural or non-natural, and may be linked by e.g. phosphorothioate bonds or natural phosphodiester bonds. Nucleotide analogs may be linked e.g. by amide bonds, peptide bonds, or any equivalent means capable of linking nucleotide analogs so as to allow the nucleotide analog string to hybridize specifically with another string of nucleotides or nucleotide analogs. The sugar moiety of a nucleotide or nucleotide analog may be a ribose or a deoxyribose, a ribose derivative, or any other molecular moiety that allows the template or complementing template to hybridise specifically to another string of nucleotides or nucleotide analogs.

[0218] Template directed synthesis: Used synonymously with template directed incorporation and templated synthesis. Template directed synthesis is the process, wherein the formation of a templated molecule comprising a sequence of covalently linked, functional groups involves contacting a string of coding elements with particular complementing elements. The process thus defines a one-to-one relationship between coding elements and functional groups, and the contacted coding element of the template directs the incorporation of the functional group into the templated molecule comprising a sequence of covalently linked, functional groups. Accordingly, there is a predetermined one to one relationship between the sequence of functional groups of the templated molecule and the sequence of coding elements of the template that templated the synthesis of the templated molecule. Thus, during the templated synthesis of the templated molecule, a functional group is initially contacting - by means of a linker moiety and/or a complementing element, or otherwise - the coding element capable of templating that particular functional group into the templated

molecule. When the template comprises or essentially consists of nucleotides, a template directed synthesis of an oligonucleotide is based on an interaction of each nucleotide with its pairing partner in the template in a one-base-to-one-base pairing manner. The interaction specifies the incorporation of complementing nucleotides opposite their base pairing partners in the template. Consequently, one base, including a heterocyclic base, from each oligonucleotide strand interact when forming specific base-pairs. This base pairing specificity may be achieved through Watson-Crick hydrogen-bonding interactions between the bases, where the bases may be natural (i.e. A, T, G, C, U), and/or non-natural bases such as those e.g. disclosed e.g. in US 6,037,120, incorporated herein by reference. Further examples of non-natural bases are e.g. PNA (peptide nucleic acid), LNA (lock nucleic acid) and morpholinos. Base pairing of oligonucleotides containing non-standard base pairs can be achieved by other means than hydrogen bonding (e.g. interaction between hydrophobic nucleobases with "complementary" structures; Berger et al., 2000, Nucleic Acids Research, 28, pp. 2911-2914). The interacting oligonucleotide strands as well as the individual nucleotides are said to be complementary. The specificity of the interaction between oligomers results from the specific base pairing of a nucleotide with another nucleotide or a predetermined subset of nucleotides, for example A base pairing with U, and C base pairing with G.

[0219] Templated: Feature of the templated molecule of the complex comprising a template linked to the templated molecule, wherein the templated molecule is obtainable by template directed synthesis using the template. Thus, one component of the complex (the template) is capable of templating the synthesis of the other component (the templated molecule). The term is also used to describe the synthesis of the templated molecule that involves the incorporation into the templated molecule of functional groups, wherein the incorporation of each functional group involves contacting a coding element with a particular functional group, or with a building block comprising said functional group, wherein the contacted coding element of the template directs the incorporation of functional groups into the templated molecule linked to the template that templated in this way the synthesis of the templated molecule. Thus, during the templated synthesis of the templated molecule, a functional group is initially contacting - either directly or by means of a linker moiety and/or a complementing element - the coding element capable of templating that particular functional group into the templated molecule.

[0220] Templated molecule: Molecule comprising a sequence of covalently linked functional groups, wherein the templated molecule is obtainable by template directed synthesis using the template. Thus, one component of the complex (the template) is capable of templating the synthesis of the other component (the templated molecule). When the template comprises or essentially consists of nucleotides, the template is capable of being amplified, wherein said template amplification results in a plurality of templated molecules, wherein each templated molecule is generated by template directed synthesis using the template. Following amplification of a template, or a complementing template, templated molecules can be generated by a template directed synthesis using either a template of coding elements or a complementing template of complementing elements as a template for the template directed synthesis of the templated molecule.

[0221] Templating: Process of generating a templated molecule.

[0222] Variant: Template or templated molecule exhibiting a certain degree of identity or homology to a predetermined template or templated molecule, respectively.

Detailed Description of the Invention

[0223] In one preferred embodiment of the present invention, there is provided a "chemical display of templated molecules" which enables the generation of a huge number of "templated polymers" (e.g. from about 10^3 to about or more than e.g. 10^{18} as described elsewhere herein), wherein each templated molecule is individually linked to a "template" that serves as identification of that individual polymer (its sequence of residues), as well as a means for amplification (many copies of the molecule can be prepared by a process that replicates the template). Preferred embodiments of the invention are disclosed in Figure 1 illustrating various steps of the method of the invention.

Step 1. Synthesis

[0224] Different monomer building blocks are synthesized. Building blocks comprise a functional entity and a complementing element that are linked by means of a cleavable linker (Figures 3 and 4). Preferred building blocks comprise a nucleotide to which have been appended a functional entity through a cleavable linker, and where the functional entity comprises or essentially consists of an "activatable" polymer unit (Figure 6).

Step 2. Incorporation

[0225] The building blocks are used as substrates in a template-dependent polymer synthesis. In one embodiment, the building blocks are nucleotide-derivatives and a polymerase is preferably used to incorporate the nucleotide-derivatives into an oligonucleotide strand according to the directions of a oligonucleotide template. As a result, a complementing template (a string of incorporated building blocks) is formed, from which the functional entities protrude. The sequence

of functional entities is determined by the sequence of coding elements, such as nucleotides, of the template.

[0226] Figure 1 describes the use of a building block that carries the selectively cleavable linker which, after polymerization and activation, is capable of linking the templated polymer to its template. Alternatively, the selectively cleavable linker can be comprised by an oligo capable of annealing upstream or downstream of the polymer-encoding portion of the template (see for example Figure 7 or 8), or the link could be to the template directly.

[0227] The building block can preferably be incorporated by an enzyme, such as for example DNA polymerase, RNA polymerase, Reverse Transcriptase, DNA ligase, RNA ligase, Taq DNA polymerase, HIV-1 Reverse Transcriptase, Klenow fragment, or any other enzyme that will catalyze the incorporation of complementing elements such as mono-, di- or polynucleotides. In some of these cases, a primer is required (for example DNA polymerase). In other cases, no primer is required (e.g., RNA polymerase).

Step 3. Polymerization

[0228] Each functional entity has preferably reacted with neighbouring functional entities to form a polymer during or after formation of the complementing template. A change in conditions, e.g., photolysis, change in temperature, or change in pH, may initiate the polymerisation either during or after complementing template formation.

Step 4. Activation

[0229] The formed polymer is preferably released from the complementing elements by cleavage of at least one linker, or a plurality of cleavable linkers, except at one or more predetermined position(s), including a single position, where the linker is not cleavable under conditions resulting in cleavage of the remaining linkers. The result is a templated polymer attached at one or more positions, preferably only at one position, to the template that encodes it.

Step 5. Selection and amplification

[0230] A selection process can subsequently be performed, wherein a huge number of different templated molecules, each attached to the template that directed its synthesis, is challenged with a molecular or physical target (e.g. a biological receptor or a surface), or is exposed to a certain screen. Templated molecules having desired characteristics (e.g., binding to a receptor) are recovered and amplified, by first amplifying the templates, and then using the templates for a new round of templated polymer synthesis. The process of selection and amplification can be repeated several times, until a polymer with appropriate characteristics (e.g., high affinity for the receptor) is isolated.

[0231] A typical selection protocol involves the addition of a population (a library) of template-templated molecule complexes to an affinity column, to which a certain molecular target (e.g., a receptor) had been immobilized. After washing the column, the binders are eluted. This eluate consists of an enriched population of template-templated molecule complexes with affinity for the immobilized target molecule. The enriched population may be taken through an amplification round, and then be subjected to yet a selection round, where the conditions optionally may be more stringent. After a number of such selection-and-amplification rounds, an enriched population of high affine binders are obtained.

[0232] When selecting for the ability of a templated molecule to become internalized into a cell, the selection step may involve a simple mixing of the population of template-templated molecule complexes with cells. After incubation (to allow the internalization of the template-templated molecule complexes), the cells are washed, and the internalized template-templated molecule complexes may be recovered by lysis of the cells. As above, the template-templated molecule complexes may be amplified and taken through further rounds of selection-and-amplification. After a number of selection-and-amplification rounds, an enriched population of templated molecules with the ability to internalize are obtained.

Building blocks - molecular design

[0233] The building blocks (also termed "monomers") is preferably of the general design shown in Figure 3 and 4. The monomer in one embodiment comprises the following elements: Complementing element-Linker-Backbone comprising reactive group(s) type II-Functional group, where the complementing element comprises or essentially consists of a recognition group and reactive group(s) type I. In this case the linker is preferably a "traceless linker", i.e., a linker that does not leave any (undesirable) molecular entity on the functional entity. Building blocks with this composition are used in for example (Figure 15, example 7).

[0234] Alternatively, the monomer may have the composition Complementing element-Linker-Functional Group-Backbone containing reactive group(s) type II, in which case the desired functional group is created as a result of cleavage of the linker. Building blocks with this composition are used in for example (Figure 17, example 1).

[0235] The functional groups must be compatible with the desired method for incorporation of complementing elements,

their polymerization and activation. Obviously, it is important to preserve the integrity of the template and the templated molecule in these processes.

[0236] Functional groups that are not compatible with the conditions of incorporation, polymerization or activation must be protected during these processes, or alternatively, the functional groups must be introduced after these processes have taken place. The latter is done by templating a functional group (e.g., an activated disulfide) that is compatible with the incorporation, polymerization and activation, and that will specifically react with a bifunctional molecule (e.g., a thiol connected to the desirable functional group, R_X), added after activation. Alternatively, functionalities may be introduced by e.g. oxidation, or any other form of treatment, of the incorporated functional entities after activation. In this way, functionalities such as components of natural effector molecules or synthetic drugs that are otherwise difficult to handle, may be incorporated.

[0237] In some embodiments of the process of the invention as described herein, there is no need for a cleavable linker, as the polymerisation reaction involves cleavage of the linker (Figure 14 and Figure 14, example 1).

[0238] When being nucleotides, the complementing elements may contain one, two or several nucleotides or nucleotide-analogs. The use of di-, tri- or longer oligonucleotides presents a number of advantages. First, a higher monomer diversity may be encoded by the template. Second, the requirements for the site of attachment of the functional entity to the complementing element becomes more relaxed. Third, there would be less bulk per mononucleotide in the formed polynucleotide, potentially leading to higher display-efficiencies. Fourth, it would allow the display of polymers with longer residue-unit-length. Also, it would allow the display of bigger functional groups.

[0239] In cases where a polymerase is employed for the incorporation of nucleotide comprising building blocks, it is preferred that the nucleotides are derivatized in a way that allows their specific and efficient incorporation into the growing strand.

[0240] More than 100 different nucleoside- and nucleotide-derivatives are commercially available or can be made using simple techniques (Eaton, Current Opinion in Chemical Biology, 1997, 1: 10-16). Moreover, many nucleotide-derivatives, modified on the bases or the riboses, are incorporated efficiently and specifically by various polymerases, in particular T7 RNA polymerase and Reverse Transcriptase (Figure 9). Nucleotides with additions of up to 300 Da have been incorporated specifically and efficiently (Wiegand et al., Chemistry and Biology, 1997, 4: 675-683; Fenn and Herman, Analytical Chemistry, 1990, 190: 78-83; Tarasow and Eaton, Biopolymers, 1998, 48: 29-37). In addition to the four natural base pairs (AT or AU, TA or UA, CG, GC), at least 8 base pairs are known to hybridise specifically, some of which are incorporated into oligonucleotides by polymerases in a template-dependent manner.

[0241] The incorporation of complementing elements may be catalyzed by chemical or biological catalysts. When the building blocks are nucleotides, particularly relevant catalysts are template-dependent DNA- and RNA-polymerases, including reverse transcriptases, and DNA- and RNA- ligases, ribozymes and deoxyribozymes. Specific examples include HIV-1 Reverse Transcriptase, AMV Reverse Transcriptase, T7 RNA polymerase and T7 RNA polymerase mutant Y639F, Sequenase, Taq DNA polymerase, Klenow Fragment (Large fragment of DNA polymerase I), DNA-ligase, T7 DNA polymerase, T4 DNA polymerase, T4 DNA Ligase, E. coli RNA polymerase, rTh DNA polymerase, Vent DNA polymerase, Pfu DNA polymerase, Tte DNA polymerase, ribozymes with ligase or replicase activities such as described in (Johnston et al., Science, May 18, 2001, pp. 1319-1325), and other enzymes that accept nucleotides and/or oligonucleotides as substrates. Mutant or engineered polymerases with improved characteristics, for example broadened nucleotide substrate specificity, and mutants in which the proofreading function has been eliminated (for example by deleting the nuclease activity), are particularly relevant. The polymerases may use single or double stranded nucleotides as templates, and produce single or double stranded nucleotide products.

[0242] Sites of modification that have been shown to be accepted by polymerases include the following non-exhaustive list of examples (See also Figure 9):

Nucleotide	Site of modification
dATP	3-position
dATP	7-position
dATP	8-position
dATP	2' (deoxyribose moiety)
dTTP	4' (deoxyribose moiety)
dGTP	7-position
dCTP	2' (deoxyribose moiety)
dUTP	2' (deoxyribose)
UTP	5-position
ATP	8-position

[0243] Terminal transferase, RNA ligases, Polynucleotide kinases and other template independent enzymes that accept nucleotides and/or oligonucleotides as substrates, including engineered or mutant variants, may be used for some of the applications and method variations described in the present invention.

[0244] It may be possible to attach the functional entities at other sites in the nucleotide, without eliminating hybridization or incorporation specificity. Particularly when employing complementing elements that are di-, tri- or polynucleotides, it may be possible to attach functional entities at these alternative sites without inhibiting specific incorporation.

Cleavable and non-cleavable linkers

[0245] A selection of cleavable linkers and protection groups, as well as the agents that cleave them, are illustrated in (Figure 10). In one aspect of the invention, the linker may be selected from the following list: Carbohydrides and substituted carbohydrides; Vinyl, polyvinyl and substituted polyvinyl; Acetylene, polyacetylene; Aryl/hetaryl, polyaryl/hetaryl and substituted polyaryl/polyhetaryl; Ethers, polyethers such as e.g. polyethyleneglycol and substituted polyethers; Amines, polyamines and substituted polyamines; Double stranded, single stranded or partially double stranded natural and unnatural polynucleotides and substituted double stranded, single stranded or partially double stranded natural and unnatural polynucleotides; Polyamides and natural and unnatural polypeptides and substituted polyamides and natural and unnatural polypeptides.

[0246] It one aspect of the invention it is preferred that linkers do not react with other linkers, complementing elements or functional entities, in the same monomer or in another monomer. Also, in some of the schemes proposed herein, it is desirable that the linker is not cleaved by the conditions of polymerization. Finally, it is preferred that the conditions of linker cleavage does not affect the integrity of the template, complementing template or functional entities.

[0247] Linkers can be cleaved in any number of ways when subjected to predetermined conditions. Linkers may e.g. be cleaved with acid, base, photolysis, increased temperature, added agents, enzymes, ribozymes or other catalysts. Examples of cleavable linkers and their respective protection groups are shown in (Figure 10), along with the conditions for linker cleavage, and the cleavage products.

[0248] To maintain a physical link between the template and the templated molecule, at least one non-cleavable linker is needed. This non-cleavable linker is preferably flexible, enabling it to expose the templated molecule in an optimal way.

Functional groups

[0249] The one or more functional groups that appear on the functional entity may be selected from a variety of chemical groups which gives the templated molecules the desired properties or serves another beneficial purpose, like higher lipophilicity for recovery purposes. A non-limiting selection of functional groups is indicated below: Hydroxy; alkoxy, Hydrogen; Primary, secondary, tertiary amines; Carboxylic acids; Carboxylic acids esters; Phosphates, phosphonates; Sulfonates, sulfonamides; Amides; Carbamates; Carbonates; Ureas; Alkanes, Alkenes, Alkynes; Anhydrides; Ketones; Aldehydes; Nitratates, nitrites; Imines; Phenyl and other aromatic groups; Pyridines, pyrimidines, purines, indole, imidazole, and heterocyclic bases; Heterocycles; polycycles; Flavins; Halides; Metals; Chelates; Mechanism based inhibitors; Small molecule catalysts; Dextrins, saccharides; Fluorescein, Rhodamine and other fluorophores; Polyketides, peptides, various polymers; Enzymes and ribozymes and other biological catalysts; Functional groups for post-polymerization/post activation coupling of functional groups; Drugs, e.g., taxol moiety, acyclovir moiety, "natural products"; Supramolecular structures, e.g. nanoclusters; Lipids; and Oligonucleotides, oligonucleotide analogs (e.g., PNA, LNA, morpholinos).

Reactive groups of type II

[0250] A variety of reactive groups II may be used in the templated synthesis. Examples of reactive groups include, but are not limited to N-carboxyanhydrides (NCA), N-thiocarboxyanhydrides (NTA), Amines, Carboxylic acids, Ketones, Aldehydes, Hydroxyls, Thiols, Esters, Thioesters, conjugated system of double bonds, Alkyl halides, Hydrazines, N-hydroxysuccinimide esters, Epoxides, Haloacetyls, UDP-activated saccharides, Sulfides, Cyanates, Carbonylimidazole, Thiazinanones, Phosphines, Hydroxylamines, Sulfonates, Activated nucleotides, Vinylchloride, Alkenes, and quinines.

Polymerization

[0251] Reactions that lead to polymer formation are termed polymerization reactions. The major reaction-classes are anionic polymerizations, cationic polymerizations, radical polymerizations, and pericyclic polymerizations.

[0252] Although polymerisation reactions in solution is achievable by state of the art methods, polymerisation of functional entities linked to an array as described herein does not constitute standard type reactions. Only a few polymerisation reactions have so far been performed in an array format, and not in connection with the methods of the present

invention. Consequently, it will be a matter of molecular design of the functional entities and their linkers and attachment points on the complementing elements (e.g. attachment to the base, ribose or phosphate of a nucleotide), as well as a matter of optimising the polymerisation conditions, in order to preferably reduce minimize or even eliminate any undesirable reactions taking place in solution while increasing or maximizing a correct template-directed polymerisation on the array.

[0253] The present invention in one embodiment employs polymerization reactions which are in principle known from the state of the art in the sense that they are routinely used in solution synthesis schemes. However, in the present invention, the reactants (reactive groups) are held in close proximity by their attachment to elements of a complementing template. This increases the local concentration significantly. Typical synthesis schemes in solution use 1 μ M-1 mM concentrations of the reactants. When arrayed as disclosed herein, the local concentration will typically be from a thousand-fold to a million-fold higher. As a result, the reactions can in principle be much more efficient. However, the reactions are preferably designed in such a way that the occurrence of undesirable side-reactions are avoided. The molecular design and the polymerization conditions according to the invention reflect this fact and can be further optimised by the skilled person searching for the polymerization conditions and molecular design that maximizes the relative template directed polymerization polymerization in solution.

[0254] Depending on the type of initiator and reactive groups, the polymerization may be initiated and/or catalyzed by changes in pH and/or temperature, addition of reactants or catalysts, enzymes or ribozymes, or light, UV or other electromagnetic radiation, etc. Particularly relevant enzymes include proteases, protein ligase (e.g., subtiligase), UDP-glycogen synthetases, CGTases and polyketide synthases. In cases where the conditions and molecular designs have been finely adjusted, so as to allow efficient polymerization of the reactants when arrayed on the complementing template, but insignificant reaction in solution, the polymerization need not be initiated. The increased local concentration in the array simply drives the polymerization.

[0255] In the case where incorporation of monomer building blocks are incorporated by an enzyme, one might fuse this enzyme with one of the enzymes mentioned above (e.g., the UDP-glycogen synthetase). This would allow the fusion-protein to first incorporate a monomer through reaction of its reactive groups type I, and right thereafter (as the now-incorporated monomer emerges from the active site of the enzyme), the other half of the fusion-protein (e.g., the UDP-glycogen synthetase) would link the functional entity of that monomer to the functional entity of the previous monomer in the complementing template.

[0256] The functional groups (or backbone structures) may have to be protected, in order to not react with the reactive groups or other components of the system during incorporation, polymerization and activation. This may be achieved using standard protection groups, some of which are mentioned in (Figure 10).

[0257] The polymerization reactions described herein below are divided into two major groups, dependent on whether the functional entity is held in a fixed orientation relative to the complementing template.

Group 1: The functional entities can rotate relative to the complementing elements (and can therefore rotate relative to the complementing template).

Direct linkage of reactive groups: The reactive group type II of one monomer react directly with the reactive group type II of another monomer.

[0258]

a). In one example, the functional entity carries two reactive groups X1 and X2 of the same kind. "Same kind" in this respect means that a given X1 can react with both an identical X1 and a non-identical X2. In (Figure 11) X1 and X2 are identical, wherefore they are both symbolized with an X. X may react with another X to form XX (Figure 11). As an example, X might be a thiol (-SH) and the resulting product a disulfide (-SS-). As another example, X could be a coumarin moiety which upon photo-induction reacts with a coumarin moiety of a neighbouring monomer (Figure 11, example 1).

In most cases, the reaction of X with X results in the loss of an atom or a molecular moiety; in the case of the thiol, for example, two protons are lost upon disulfide formation. The fact that XX (the result of the reaction between two reactive groups type II) does not contain all the components of X plus X, is indicated in (Figure 5, A) where in fact both types of reactive groups (both type I and II) upon reaction forms a molecular entity that is slightly different from the reactive groups (symbolized by overlapping circles in the figure).

b). The two reactive groups type II may be of a different kind. "Different kind" here means that they react with different types of molecules. For example, X and Y might be nucleophiles and electrophiles, respectively. X and Y react to form XY (Figure 12). For longer templated molecules, free rotation of the functional entities relative to the complementing template represents a potential problem, if the functional entities do not react until many monomers have been incorporated. In this case, cluster formation (Figure 13) may result, which decreases the amount of full-length,

templated polymers. The problem is, however, only significant for longer polymers; from experience with biological display of α -peptides, such as phage-display and polysome-display, it is known that display efficiencies as low as 1 % is enough to isolate peptides with high binding affinity for a given target.

[0259] In certain cases the incorporated monomers react right after their incorporation into the complementing template (at which time the next monomer in the complementing template has not been incorporated yet). Therefore, the last incorporated monomer will react with the second-last incorporated monomer, which is already part of the complementing template. As a result, cluster formation will not be a significant problem in this case.

[0260] X and Y might be an amine and a carboxylic acid. In the presence of carbodiimide, X and Y will react to form an amide XY.

[0261] Another version of this type of polymerization involves the simultaneous polymerization and activation of the polymer (Figure 14). The monomers do not contain a separate linker moiety; rather, the polymerization reaction leads to activation (release of the functional entity from the complementing template). In this scheme, each monomer is incorporated and reacts with the previously incorporated monomer, leading to the previously incorporated monomers release from the complementing template, before the next monomer is incorporated. (Figure 14, example 1) shows the use of this principle for the formation of polyamides, in this case β -peptides. The method may obviously be used for other peptides also, as well as any kind of polyamides.

[0262] By appropriate design of the monomers, one may generate other types of polymer bonds by nucleophilic substitution reactions, including amide, ester, carbamate, carbonate, phosphonate, phosphodiester, sulfonamide, urea, carbopeptide, glycopeptide, saccharide, hydrazide, disulfide and peptoid bonds.

[0263] In (Figure 14, example 2) the same principle is applied to a different type of reaction, a "rolling circle polymerization reaction". An alkyl sulfonate is here used as an efficient leaving group, to drive the formation of a secondary amine. The result is a functionalized polyamine, attached at one end to the template that directed its synthesis. In an analogous way, one may generate polyether and poly-thioether using similar molecular designs. Polymers that can be generated by the use of the principles described in (Figure 14 and 14, example 1 and 2) include oligodeoxynucleotides, oligoribonucleotides, chimeric oligonucleotides, oligonucleotide analogs (e.g., PNA, LNA), peptoids, polypeptides and p-peptides.

"Fill-in" polymerization: An additional molecule mediates linkage between reactive groups type II from neighbouring monomers.

[0264]

a). The functional entity carry one or two reactive groups X1 and X2 of the same kind, where X1 cannot react with another X1 or X2. For example, X1 and X2 could be a primary and secondary amine, respectively. In order to polymerize, a compound of the kind Y1-linker-Y2 is added, where Y1 and Y2 are of the same kind. Y can react with X, but is sterically or chemically excluded from reaction with another Y. As a result, a X-Y-Y-X is formed (Figure 15). As an example, X could be an amine, and Y a activated ester. Upon reaction, this would form an ester-ester bond (X-Y-Y-X) between two functional entities.

It is preferred that the two X of one monomer does not to any significant extent react with the same Y-linker-Y molecule. This can be prevented e.g. by imposing steric constraints on the molecules, e.g., Ys in the Y-linker-Y molecule are further apart than the Xs in the monomer.

(Figure 15, example 2) provides two examples of "fill-in" polymerization of polyamides. In (Figure 15, example 2, A and B), the reactive groups type II are amines, and the Y-linker-Y molecule is a dicarboxylic acid or an activated di-ester. In either case, the resulting product is a di-amide polymer. Obviously, the kind of X and Y could be switched, so that in the examples X was a carboxylic acid and Y an amine. Other combinations of X and Y, and their resulting bonds, are given in Figure 25, which summarizes some of the kinds of polymers that may be generated by the various polymerization principles described in the present patent..

For certain reactions, the linking molecule need only contain one reactive group X. An example is shown in (Figure 15, example 3A), where the functional entities contain two reactive groups type II (amines), and the added molecule is a phosgen equivalent such as 1,1'-carbonyldiimidazole. The resulting bond is an urea bond. In (Figure 15, example 5) the monomers contain two hydroxyl groups, to which is added an activated phosphodiester or an activated phosphine derivative such as a bisaminophosphine following activation with tetrazole and oxidation with *tert*-butyl-hydroperoxide. The result is a phosphodiester bond.

The functional entity may in certain cases contain only one reactive group type II. An example is shown in (Figure 15, example 6), where an activated phosphodiester makes up the only reactive group type II of the monomer. Upon reaction with a di-hydroxy, a phosphodiesterbackbone is formed.

As yet another example of fill-in polymerization, (Figure 15, example 7) shows the pericyclic reaction of dienes

(functional entity) reacting with alkenes (linking molecule), to form a polycyclic compound.

A general consideration when using the fill-in polymerization principle, is the number of stereoisomers templated by the same template. For example, in (Figure 15, example 4, A), the functional entity contains two primary amines. The functional entity is connected to the complementing template through a chiral carbon. The functional entity may rotate freely around the bond that connects this chiral atom with the complementing template. Therefore, the reaction of the amines (X) with the linking molecules (activated carbonyls, (Y)) will result in the formation of 2^n different isomers, where n is the number of residues of the polymer.

The isomers represent a significant increase in diversity. For example, for a 10-meric polymer, the chirality represents a 1024-fold increase in diversity. This may in certain cases be an advantage, for example if the monomer diversity is low, or if the desire is to make short polymers. However, such "scrambling" of the genetic code (i.e., one template encodes different polymer structures) also decreases the stringency of the selection process. Therefore, in certain cases scrambling is not desirable. One may then choose to connect the functional entities to the complementing elements via non-chiral atoms. In (Figure 15, example 4, B) is shown an example of an achiral atom (nitrogen) connecting the functional entity with the complementing template. Scrambling may involve cases where one complementing element specifies different isomers (as described above), and scrambling may also involve cases where a complementing element specifies slightly different or entirely different functional entities.

b). The functional entity carries two different reactive groups of type II, X and S (Figure 16). X does not react with X or S, and vice versa. Before, during or after incorporation of monomers, molecules of the form T-linker-Y are added. X may react with Y, and S may react with T, leading to formation of X-S-T-Y linkages between the functional entities. It is important to ensure that X and S of one functional entity cannot react with T and Y of one linking molecule. This may be ensured by appropriate design of the structure of the functional entities and linking molecule. (Figure 16, example 1) provides an example of a functional entity with different reactive groups type II, in this case an azide and a hydrazide (X and S), and a linking molecule with different reactive groups, in this case a phosphine and a ketone (T-linker-Y).

[0265] For longer templated molecules, free rotation of the functional entities relative to the complementing template represents a potential problem, if the functional entities do not react until many monomers have been incorporated. In this case, cluster formation (Figure 13) may result, which decreases the amount of full-length, templated polymers. The problem is, however, only significant for longer polymers, as explained above. If the linking molecules are present during incorporation of the complementing elements, the incorporated monomers may react with the linking molecules right after their incorporation, or in the case of enzyme-mediated incorporation, as soon as they emerge from the active site of the enzyme. Cluster formation will not be a significant problem in these cases.

"Zipping" polymerization: The Polymerization reaction travels from one end of the template to the other.

[0266] In this approach, the polymerization reaction is directional, i.e., the reaction cascade starts at one end of the complementing template, and the reactions migrate to the other end of the complementing template, thereby forming a templated polymer.

a). General principle (Figure 18). After incorporation of some or all of the monomer building blocks, polymerization is initiated from one end of the template, and travels down the template. For example, the initiator may be coupled to the first or last complementing element to be incorporated, or it may be coupled to the primer used in DNA polymerase-mediated incorporation of nucleotide-derivatives. Either way, the initiator will react with the neighbouring monomer's reactive group type II, which induces a change in the functional entity of that monomer, allowing this monomer to react with the next monomer in the chain, and so on. Eventually, all the monomers have reacted, and a polymer has been formed.

It may be desirable to protect the initiator, keeping it from reacting with the neighbouring monomer until incorporation is complete, whereafter the initiator is deprotected. This allows the experimenter to remove all non-incorporated initiators and complementing elements before activating the initiator, which eliminates reaction in solution between the initiator and the complementing elements.

Deprotection of the initiator may be by change in pH or temperature, exposure to electromagnetic radiation, or addition of an agent (that removes a protection group, or introduces an initiator at a specific position, or ligates or coordinates to the naïve initiator, to make it a more potent initiator). The agent could be a chemical catalyst or an enzyme, for example an esterase or peptidase.

b). Zipping by radical polymerization (Figure 18, example 1). The initiator is a alkyl-iodide, and the functional entities contain a double bond. Upon addition of a radical initiator, for example ammonium persulfate, AIBN (azobis-isobutyronitrile) or other radical chain reaction initiators, a radical chain reaction is initiated, whereby the alkenes react

to form an extended, functionalized alkane. Eventually, the polymer has been made, and it is activated (cleaved from the complementing template, except at one point). The radical remaining at the end of the polymer may be quenched by a radical termination reaction.

5 c). Zipping by cationic polymerization (Figure 18, example 2). The initiator is a Lewis acid. Upon deprotection with acid or other initiation reagent, a cation is generated. The carbocation attacks the double bond of the neighbouring monomer, and as a result a carbocation is generated in this monomer. Eventually, the full-length polymer has been formed, and the polymer is activated.

10 d). Zipping by nucleophilic (anionic) polymerization (Figure 18, example 3). In this example, the initiator is a protected hydroxyl anion. The functional entity carries a peroxide. Upon deprotection of the initiator the hydroxyl-anion is formed (e.g., by alkaline deprotection). Under basic conditions, the initiator attacks the neighbouring epoxide at the least hindered carbon in the ring. This in turn generates a hydroxyl-anion, which attacks the neighbouring epoxide. Eventually, the full polymer is formed, and the polyether may be activated. In this example, all of the linkers that
15 connect the polyether to the complementing template are cleaved.

This type of polymerization is also an example of ring-opening polymerization.

20 e). Zipping polymerization by ring opening (Figure 19). The general principle of ring-opening polymerization is shown. The initiator attacks the reactive group X of the neighbouring monomer. X is part of a ring structure, and as a result of the reaction between the initiator and X, the ring opens, whereby the other reactive group of the monomer is activated for attack on the next monomer in the array. Polymerization travels down the strand, and eventually the full-length polymer has been formed.

25 f). β -peptide formation by ring-opening polymerization of carboxyanhydrides (Figure 19, example 1). The deprotected initiator, a nucleophilic amine, attacks the most electrophilic carbonyl of the N-thiocarboxyanhydride, to form an amide. CSO is released, generating a primary amine, which then attacks the next monomer in the array. Eventually polymerization is complete, and the polymer may be activated, creating a β -peptide attached to the complementing template or template through its C-terminal end. The principle may be used to form other types of peptides, for example D- and L- form mono- and disubstituted α -peptides, β -peptides, γ -peptides, carbopeptides and peptoids (poly N-substituted glycine), and other types of polyamides. Also, the principle can be employed for the generation
30 of other polymers, such as polyesters, polyureas, and polycarbamates.

35 g). β -peptide formation by ring-opening polymerization of thiazinanone units (Figure 19, example 2). The deprotected initiator attacks the cyclic thioester, to form an amide. As a result, the ring breaks down to release a free thioketone. This generates an amine, which may now attack the thioester of the next monomer in the array. When polymerization has travelled to the other end of the template, it is activated, generating a β -peptide attached to its template through the C-terminal end.

The principle may be used to form other types of peptides, for example D- and L-form mono- and disubstituted α -peptides, β -peptides, γ -peptides, carbopeptides and peptoids (poly N-substituted glycine), and other types of polyamides. Also, the principle can be employed for the generation of other polymers, such as polyesters, polyureas,
40 and polycarbamates.

45 h). Zipping polymerization by rearrangement (Figure 20). Upon activation of the initiator, which in this case could be an electrophile, the reactive group type II of the neighbouring monomer attacks the initiator, and as a result, releases the initiator from the complementing element. In the attacking monomer, the reaction of Y with the initiator leads to a rearrangement of the monomer, which results in activation of X, the other reactive group type II of the monomer (for example, the reorganization creates a nucleophile). Then, the next monomer in the array attacks this nucleophile. Eventually, full-length polymer has been formed, attached at one end to the template that directed its synthesis.

50 i). Zipping and activation in one step (Figure 21). By appropriate design of the functional entities used for ring-opening polymerization, activation may be achieved as a direct result of the polymerization reaction. By simply turning the functional entity upside-down, i.e., attach the portion of the ring that does not get incorporated into the final polymer to the complementing template, saves the experimenter an activation step (compare Figure 21 and Figure 19). As a specific example, attachment of the 2,2-diphenylthiazinanone ring structure of (Figure 19, example 2) to the complementing elements through one of the phenyl groups would lead to activation as a result of the polymerization reaction.
55

Group 2: The functional entity cannot rotate freely relative to the complementing element

[0267] In this embodiment, the X and Y reactive groups type II are held in the desired orientation relative to the complementing template (Figure 22, A). X and Y can therefore react, or react with a linker molecule, without the risk of cluster formation (compare with Figure 13).

[0268] The functional entity may be held in the fixed orientation by a double bond, or by bonds to different atoms in the complementing element. (Figure 22, B) provides an example, where the functional entity is covalently coupled to the two bases of a dinucleotide (the complementing element is a dinucleotide, the functional entity contains a dipeptide, and the reactive groups are the amine and the ester moieties, respectively).

[0269] Polymers that can be made by this method include all of the polymers mentioned in the non-zipping polymerizations above, for example peptides, amides, esters, carbamates, oximes, phosphodiester, secondary amines, ethers, etc.

[0270] The figures 23 to 25 relates to how a cluster formation can be avoided by covalent constraints.

[0271] A special situation arises employing bifunctional functional entities (FE) due to a potential free rotation around the linker-nucleotide bond. A bifunctional FE bears two different reactive groups 'X' and 'Y', e.g. both a nucleophile and an electrophile, where 'X' on one FE is meant to react with 'Y' on the neighbour FE either directly or through a cross-linking agent. If all linker-FE units orient identically with respect to the parent nucleotide, directional polymerization will take place and a complete product of say 5 units will be formed ('Figure 13 top'). However, rotation around the linker-bond of some, but not all, linker-FE entities so that the relative orientation of the two functionalities reverses leads to a clustering situation, where the reacting groups are arranged so that reaction can take place in two different directions ('Figure 13 bottom'). This unfavourable situation can be avoided by using fixed functional entities thereby preventing rotation around the nucleotide-linker bond. Fixing the FEs may be obtained by attaching the FE not by one but by two covalent bonds (i.e. two linkers) to the nucleotide. The additional bond may be formed directly by one of the functionalities, or the two reactive groups may be attached separate 'arms' on a fixed backbone. In the first situation the additional bond may be broken during the reaction, whereas the additional bond in the latter should be constructed so that also this bond is cleavable after reaction, to release the final product.

The primary attachment points of the linker-FE units are typically within the bases of the nucleotides, preferably position C5 in T/U and C or position C7 in deaza A and deaza G. In order to construct an efficient inhibition of linker-bond rotation, the second bond should preferably be somewhat distant from this attachment point. That is, the second attachment could be anywhere in a neighbour nucleotide, preferably in the base or in the sugar part, it could be a second atom in the same base, preferably position C6 in T/U and C or position C8 or N6 in (deaza)A or (deaza)G, or it could be an atom of the sugar moiety, preferably position C2 or C3. Explicit examples are given in Figure 23.

[0272] It should be noted that nucleotides bearing some of these doubly-attached linkers may be necessary to incorporate by other means than using a polymerase. An alternative to polymerase incorporation is the imidazole approach described elsewhere herein.

[0273] In order to show the effect of covalently constraining the FE to ensure directional polymerization a series of computer calculations have been performed on two examples shown in Figure 23A and 23B. The purpose is to analyse various modes of attack for each linker-FE construction, estimating the most probable reaction and thereby the most probable product. Therefore, the conformational space covered by the linker-FE unit and the zones occupied by the reactive groups needs to be estimated.

[0274] The conformational space of a specific linker-FE system, i.e. the range of the FE, can be estimated by doing a conformational search. Conformational searches can be performed employing various different software and within these programs using different searching methods and is standard knowledge within the field. For systems of the size mentioned in this text it is not possible to perform a converged conformational search, that is, to ensure that enough steps have been taken so that the complete potential energy surface has been covered and thereby that the located minimum energy conformation is truly the global minimum for the molecule. However, the purpose of these calculations is to get a picture of the space allowed to be covered by a linker-FE unit and thereby to estimate the most likely approach of attack between two FEs and the possibility for the reacting groups to get within reaction distance. Efficient conformational searching methods employing a rather limited number of steps fulfil this purpose.

[0275] By *conformations* are here meant individual structural orientations differing by simple rotation about single bonds. Different conformations may in addition give rise to different overall *configurations*, by which is meant an overall arrangement of the two reactive groups on all modified nucleotides that give rise to one specific direction of reaction. That is, four linker-FE units arranged with all 'X's' in the same direction corresponds to one specific configuration, and four linker-FE units arranged e.g. with two 'X's' pointing in one direction and the two other in the opposite direction corresponds to another specific configuration. Within one configuration many different conformations are possible, but all of these result in the same 'most probable' product since the overall orientation (direction) of reactive groups is preserved.

[0276] The calculations performed in this investigation have been performed employing the MacroModel7.2 software

from Schrödinger Inc (MMOD72). Within this program package a series of different searching protocols are available, including the 'Mixed Monte Carlo Multiple Minimum/Low Mode' method (MCMM/LM), shown to be very effective in locating energy minima for large complicated systems.

5 Computational details

[0277] Double-stranded DNA with the base sequence 5'-GCTTTTATAG-3' (upper strand) (example displayed in Figure 24) or 5'-GCTTTTAG-3' (upper strand) (example displayed in Figure 25) was built using HyperChem7 from HyperCube Inc in the most frequent B-conformation. The linker-FE units were built using ChemDraw Ultra 6.0 and Chem3D Ultra 6.0 from ChemOffice. Linker-FE units and DNA were imported into MMOD72. The linkers were then fused to the corresponding nucleotides using the build feature in MMOD72, fusing the methyl carbon atom of the T nucleotides with the appropriate linker atom, in effect creating a modified U nucleotide. In all calculations all DNA atoms were kept frozen, that is, were not allowed to move, in order to decrease the size of the systems and to avoid distortions within the DNA strand. The total system was energy minimised (keeping the DNA atoms frozen) employing the OPLS_AA force field supplied in MMOD72. It was necessary to constrain the dihedral angle bridging the nucleotide and the linker, i.e. the dihedral of N1, C6, C5 and the first linker atom was set to 180.0 degrees and a force constant of between 100 and 1000 applied. Without the constraint none of the MMOD72 force fields preserved the plane, presumably due to a too weak out-of-plane force constant for this particular dihedral.

[0278] Conformational analyses were performed using the MCMM/LM method, running 2000 steps with an energy cutoff of 50 kJ/mol, and with a minimum and maximum distance travelled by the fastest moving atom of 3 and 8 Å, respectively. Depending on the specific size of the system, 11-19 torsions were allowed to vary, and finally each conformer was minimized by 500-1000 PR Conjugate Gradient steps (this resulted in most conformers being minimized to within a convergence threshold of 0.05 kJ/mol). The chirality of chiral atoms was preserved during the calculations. In addition, for the systems with covalently constrained linkers one ring closure bond (either the formed amide bond or the base-S bond) was chosen within each ring.

Results

[0279] One way of creating a second attachment point is to link one of the functional entities via a breakable bond to a neighbour nucleotide. In effect, this means that dinucleotides instead of mononucleotides are employed and also that the length of the FE is increased. Using this approach, a series of valid attachment points exist; Figure 23A is an example of attachment to the same position of the neighbour base. Linker 1A is constructed from a β -dipeptide, with the amino end connected to the 5' base via a disulfide bond prone for reductive cleavage and the carboxy-end directly linked to the 3' base. When reaction takes place the amino group from one dinucleotide-linker-FE unit will break the ester bond of the preceding dinucleotide-linker-FE. Employing the same linker-FE unit without the second attachment point corresponds to employing dipeptides on one-nucleotide-spaced mononucleotides. Such a linker-FE bears two reactive groups on separate arms and has free rotation about the nucleotide-linker bond and is therefore an example of a bifunctional linker-FE which bears the risk of cluster formation in case of lack of directional polymerization. Running 2000 conformational search steps of the singly-attached linker results in 490 unique conformations (849 conformations after 500 minimization steps, 490 after additional 500 steps) with the 'global' minimum located once. The lowest-energy conformation which results in a complete product has rank 8 and is shown in Figure 24A and the resulting most probable product (still attached the DNA backbone) in Figure 24B. As can be seen, the reactive groups arrange with all amino groups upwards and all carboxy groups downwards, and the two reactions that are required to give a complete product are straight-forward. The released complete product is shown as Figure 24H. However, by far the most conformations, including the 'global' minimum, do not have this overall configuration. Figure 24C shows the conformation of second highest rank and the most probable product is depicted in Figure 24D. As can be seen, this arrangement of the reactive groups results in the formation of an incomplete product. The two linker-FE units in the 3' end have formed an amide bond, but the 5' linker-FE unit has the opposite overall orientation resulting in two carboxy groups (one from the 5' linker-FE unit and one from the merged 3' linker-FE units) being the two close reactive groups and thus no reaction is possible. Release of this product therefore results in a dimer (and a monomer); the dimer is depicted in Figure 22. Of the 364 unique conformations within 10 kJ/mol of the located minimum approximately 330 results in the formation of various incomplete products.

[0280] Running 2000 conformational search steps of the doubly-attached linker results in 125 unique conformations with the 'global' minimum located nine times. This minimum energy conformation is shown in Figure 24E, where all FEs are seen to arrange with the amino groups pointing downwards and carboxy groups upwards. Clearly, this overall configuration is the only one possible for the doubly-attached linker, giving rise to only one probable product shown in Figure 24F (still attached the DNA backbone). Release of this product gives the complete three-unit product, Figure 24G.

[0281] Thus, this example shows first of all that rotation around nucleotide-linker bonds do result in (many) configura-

rations unable to form complete products. However, another important issue is the difference in complete products formed. The FEs employed in this example are constructed from unsubstituted β -amino acids and therefore there is no difference between the complete products shown in Figure 24 G and H. However, using singly-attached FEs the polarity of the formed products can change (i.e. free amino group from the 3' attached FE or free amino group from the 5' attached FE) and thereby potentially very different products can be formed. By employing fixed functional entities only one overall configuration is possible and only one product with one specific polarity can be formed.

[0282] Another possibility of attachment point is the sugar of the parent nucleotide, as exemplified in Figure 23 B, C, and D. This choice allows the employment of mononucleotides in stead of linked dinucleotides as mentioned above. Both hydrogens of C2 can be replaced by linker atoms, however, for shorter ring structures it is preferred to use the one facing the same plane as the base does. Carbon 3 of the sugar moiety forms a linkage to the phosphate group, but there is still one attachment possibility left which can be utilised for linker fixation purposes. The same holds for C1, however the space around this substitution possibility is limited. Carbon atoms 4 and 5 of the sugar moiety are quite distant from the base attachment point and therefore require large ring systems to be utilised for this purpose.

Linker-FE 1 B is constructed from a γ -amino acid attached via a disulfide bond prone for reductive cleavage to the C5 position of T/U. The linker-FE unit 1 B is therefore another typical example of a bifunctional linker-FE system capable of rotation of the nucleotide-linker bond which bears the risk of cluster formation due to lack of directional polymerization. A fixation of this FE is shown in example 1 B (right) and utilises the C2 position at the same side of the plane as the base. The FE now contains a γ -amino acid linked through the carboxyl group to the sugar via a hydrolysable ester bond and in the amino end to the C5 position of T/U via a disulfide bond prone for oxidation. Doubly-attached linker-FE unit 1B is therefore a bifunctional linker-FE with one reactive group free and the other providing the second attachment. Using almost the same linker-FE unit but letting the carboxyl end free by introducing a second ester group as a hydrolysable linker is shown in example 1C. Computational analyses of linker-FEs 1 B and 1 C result in similar conclusions, and results below refer to linker 1B.

[0283] Conformational searches of the two different schemes clearly reveal the effect of preventing rotation of the linker bond by additional covalent attachment.

Running 2000 conformational search steps of the singly-attached linker-FE results in 445 unique conformations with the 'global' minimum located once. This conformation is shown in Figure 25A and the resulting most probable product (still attached the DNA backbone) in Figure 25B. As can be seen this product is the complete product, that is, all four units are linked together via amide bonds. The released complete product is shown as Figure 25G. However, many other overall configurations are possible for this system, with one example shown in Figure 25C. The most probable product resulting from the 3C configuration is depicted in Figure 25D and as can be seen, this arrangement of reactive groups results in the formation of an incomplete product, that is, the linker-FE units are linked two and two together with no possibilities of a merging reaction. Release of this product results in two dimers, depicted in Figure 25H. Of the 334 unique conformations within 10 kJ/mol of the located minimum approximately 215 results in formation of various incomplete products.

[0284] Running 2000 conformational search steps of the doubly-attached FE results in 386 unique conformations with the 'global' minimum located twice. This conformation is shown in Figure 25E and the resulting most probable product (still attached the DNA backbone) in Figure 25F. However, since there are no possibilities of interchange of reactive groups, the conformations differ only by minor variations in dihedrals (e.g. rotation of the CH_2NH_2 group). Clearly, only one overall configuration is possible for the doubly-attached FE, giving rise to only one probable product, the complete four-unit product (Figure 25G).

[0285] Thus, the computational investigations clearly show that there is extensive rotation around nucleotide-linker bonds and that this flexibility will result in a significant proportion of the formed products not being complete. The calculations also show that using covalently fixed functional entities is one way to prevent linker rotation and thereby effectively secure unidirectional polymerisation. In addition, the complete products that do result from using unconstrained FEs form a diverse group, since there is more than one possibility of arranging the reactive groups in a way that allows reactions between all units to happen. Naturally, these tendencies will be even more pronounced using more than three to four linker-FE units as was applied in these examples.

Building blocks capable of transferring functional entities.

[0286] The following section describes the formation and use of monomer building blocks capable of transferring a functional entity from one monomer building block to another monomer building block, i.e. two functional entities of two monomer building blocks react, whereby one functional entity is cleaved from its monomer building block under the conditions applied.

General Section

Protection and deprotection of maleimide derivatives:

[0287]

[0288] Maleimide derivatives (e.g. R = H, alkyl, aryl, alkoxy etc.) may at any step below, be present in a protected form. Protection is achieved by reaction with furan. Deprotection may be achieved by thermolysis, as described by Masayasu et al., J. Chem. Soc., Perkin Trans. 1 (1980) 2122.

A. Acylation reactions

General route to the formation of acylating monomer building blocks and the use of these:

[0289]

[0290] N-hydroxymaleimide (1) may be acylated by the use of an acylchloride e.g. acetylchloride or alternatively

acylated in e.g. THF by the use of dicyclohexylcarbodiimide or diisopropylcarbodiimide and acid e.g. acetic acid. The intermediate may be subjected to Michael addition by the use of excess 1,3-propanedithiol, followed by reaction with either 4,4'-dipyridyl disulfide or 2,2'-dipyridyl disulfide. This intermediate (3) may then be loaded onto an oligonucleotide carrying a thiol handle to generate the monomer building block (4). The reaction of this monomer building block with an

amine carrying monomer building block is conducted as follows:

The template oligonucleotide (1 nmol) is mixed with a thio oligonucleotide loaded with a building block e.g. (4) (1 nmol) and an amino-oligonucleotide (1 nmol) in hepes-buffer (20 μ L of a 100 mM hepes and 1 M NaCl solution, pH=7.5) and water (39 μ L). The oligonucleotides are annealed to the template by heating to 50 °C and cooled (2 °C/ second) to 30 °C. The mixture is then left o/n at a fluctuating temperature (10 °C for 1 second then 35 °C for 1 second), to yield template bound (5).

B. Alkylation and C. Vinylation reactions

General route to the formation of alkylating/vinylation monomer building blocks and use of these:

[0291] Alkylating monomer building blocks may have the following general structure:

R¹ = H, Me, Et, iPr, Cl, NO₂

R² = H, Me, Et, iPr, Cl, NO₂

[0292] R¹ and R² may be used to tune the reactivity of the sulphate to allow appropriate reactivity. Chloro and nitro substitution will increase reactivity. Alkyl groups will decrease reactivity. Ortho substituents to the sulphate will due to steric reasons direct incoming nucleophiles to attack the R-group selectively and avoid attack on sulphur. E.g.

[0293] 3-Aminophenol (**6**) is treated with maleic anhydride, followed by treatment with an acid e.g. H_2SO_4 or P_2O_5 and heat to yield the maleimide (**7**). The ring closure to the maleimide may also be achieved when an acid stable *O*-protection group is used by treatment with or Ac_2O with or without heating, followed by *O*-deprotection. Alternatively reflux in Ac_2O , followed by *O*-deacetylation in hot water/dioxane to yield (**7**). Further treatment of (**7**) with SO_2Cl_2 with or without triethylamine or potassium carbonate in dichloromethane or a higher boiling solvent will yield the intermediate (**8**), which may be isolated or directly further transformed into the aryl alkyl sulphate by the quench with the appropriate alcohol, in this case MeOH, whereby (**9**) will be formed. The organic building block (**9**) may be connected to an oligo nucleotide, as follows.

[0294] A thiol carrying oligonucleotide in buffer 50 mM MOPS or hepes or phosphate pH 7.5 is treated with a 1-100 mM solution and preferably 7.5 mM solution of the organic building block (**9**) in DMSO or alternatively DMF, such that the DMSO/DMF concentration is 5-50%, and preferably 10%. The mixture is left for 1-16 h and preferably 2-4 h at 25 °C. To give the alkylating in this case methylating monomer building block (**10**).

[0295] The reaction of the alkylating monomer building block (**10**) with an amine carrying monomer building block may be conducted as follows:

The template oligonucleotide (1 nmol) is mixed with a thio oligonucleotide loaded with a building block (1 nmol) (**10**) and an amino-oligonucleotide (1 nmol) in hepes-buffer (20 μL of a 100 mM hepes and 1 M NaCl solution, pH=7.5) and water (39 μL). The oligonucleotides are annealed to the template by heating to 50 °C and cooled (2 °C/ second) to 30 °C. The mixture is then left o/n at a fluctuating temperature (10 °C for 1 second then 35 °C for 1 second), to yield the template bound methylamine (**11**).

[0296] A vinylating monomer building block may be prepared and used similarly as described above for an alkylating monomer building block. Although instead of reacting the chlorosulphonate (**8** above) with an alcohol, the intermediate chlorosulphate is isolated and treated with an enolate or *O*-trialkylsilylenolate with or without the presence of fluoride. E.g.

Formation of the vinylating monomer building block (13):

[0297] The thiol carrying oligonucleotide in buffer 50 mM MOPS or hepes or phosphate pH 7.5 is treated with a 1-100 mM solution and preferably 7.5 mM solution of the organic building block (12) in DMSO or alternatively DMF, such that the DMSO/DMF concentration is 5-50%, and preferably 10%. The mixture is left for 1-16 h and preferably 2-4 h at 25 °C. To give the vinylating monomer building block (13).

[0298] The sulfonylester (13) may be used to react with amine carrying monomer building block to give an enamine (14a and/or 14b) or e.g. react with a carbanion to yield (15a and/or 15b). E.g.

[0299] The reaction of the vinylating monomer building block (**13**) and an amine or nitroalkyl carrying monomer building block may be conducted as follows:

The template oligonucleotide (1 nmol) is mixed with a thio oligonucleotide loaded with a building block (1 nmol) (**13**) and an amino-oligonucleotide (1 nmol) or nitroalkyl-oligonucleotide (1 nmol) in 0.1 M TAPS, phosphate or hepes-buffer and 300 mM NaCl solution, pH=7.5-8.5 and preferably pH=8.5. The oligonucleotides are annealed to the template by heating to 50 °C and cooled (2 °C/ second) to 30° C. The mixture is then left o/n at a fluctuating temperature (10 °C for 1 second then 35° C for 1 second), to yield template bound (**14a/b** or **15a/b**). Alternative to the alkyl and vinyl sulphates described above may equally effective sulphonates as e.g. (**31**) (however with R" instead as alkyl or vinyl), described below, be prepared from (**28**, with the phenyl group substituted by an alkyl group) and (**29**), and be used as alkylating and vinylating agents.

D. Alkenylation reactions

General route to the formation of Wittig and HWE monomer building blocks and use of these:

[0300] Commercially available building block (**16**) may be transformed into the NHS ester (**17**) by standard means, i.e. DCC or DIC couplings.

An amine carrying oligonucleotide in buffer 50 mM MOPS or hepes or phosphate pH 7.5 is treated with a 1-100 mM solution and preferably 7.5 mM solution of the organic building block in DMSO or alternatively DMF, such that the DMSO/DMF concentration is 5-50%, and preferably 10%. The mixture is left for 1-16 h and preferably 2-4 h at 25 °C. To give the phosphine bound monomer building block (**18**). This monomer building block is further transformed by addition of the appropriate alkylhalide, e.g. *N,N*-dimethyl-2-iodoacetamide as a 1-100 mM and preferably 7.5 mM solution in DMSO or DMF such that the DMSO/DMF concentration is 5-50%, and preferably 10%. The mixture is left for 1-16 h and preferably 2-4 h at 25 °C. To give the monomer building block (**19**). Alternative to this, may the organic building block (**17**) be P-alkylated with an alkylhalide and then be coupled onto an amine carrying oligonucleotide to yield (**19**).

[0301] An aldehyde bound monomer building block (**20**), e.g. formed by the reaction between the NHS ester of 4-formylbenzoic acid and an amine carrying oligonucleotide, using conditions similar to those described above, will react with (**19**) under slightly alkaline conditions to yield the alkene (**21**).

[0302] The reaction of monomer building blocks **(19)** and **(20)** may be conducted as follows:

The template oligonucleotide (1 nmol) is mixed with monomer building block **(19)** (1 nmol) and **(20)** (1 nmol) in 0.1 M TAPS, phosphate or hepes-buffer and 1 M NaCl solution, pH=7.5-8.5 and preferably pH=8.0. The reaction mixture is left at 35-65 °C preferably 58 °C over night to yield template bound **(21)**.

As an alternative to **(17)** may phosphonates **(24)** be used instead. They may be prepared by the reaction between diethylchlorophosphite **(22)** and the appropriate carboxy carrying alcohol. The carboxylic acid is then transformed into the NHS ester **(24)** and the process and alternatives described above may be applied. Although instead of a simple P-alkylation, the phosphite will undergo Arbuzov's reaction and generate the phosphonate. Monomer building block **(25)** benefits from the fact that it is more reactive than its phosphonium counterpart **(19)**.

E. Transition metal catalyzed arylation, hetaylation and vinylation reactions

[0303] Electrophilic monomer building blocks (**31**) capable of transferring an aryl, hetaryl or vinyl functionality may be prepared from organic building blocks (**28**) and (**29**) by the use of coupling procedures for maleimide derivatives to SH-carrying oligonucleotide's described above. Alternative to the maleimide, may NHS-ester derivatives prepared from e.g. carboxybenzensulfonic acid derivatives, be used by coupling of such to an amine carrying oligonucleotide. The R-group of (**28**) and (**29**) is used to tune the reactivity of the sulphonate to yield the appropriate reactivity.

[0304] The transition metal catalyzed cross coupling is conducted as follows:

A premix of 1.4 mM Na_2PdCl_4 and 2.8 mM $\text{P}(\text{p-SO}_3\text{C}_6\text{H}_4)_3$ in water left for 15 min was added to a mixture of the template oligonucleotide (1 nmol) and monomer building block (**30**) and (**31**) (both 1 nmol) in 0.5 M NaOAc buffer at pH=5 and 75 mM NaCl (final $[\text{Pd}]=0.3$ mM). The mixture is then left o/n at 35-65 °C preferably 58 °C, to yield template bound (**32**).

$R'' = \text{aryl, hetaryl or vinyl}$

[0305] Corresponding nucleophilic monomer building blocks capable of transferring an aryl, hetaryl or vinyl functionality may be prepared from organic building blocks type (35).

[0306] This is available by estrification of a boronic acid by a diol e.g. (33), followed by transformation into the NHS-ester derivative. The NHS-ester derivative may then be coupled to an oligonucleotide, by use of coupling procedures for NHS-ester derivatives to amine carrying oligonucleotide's described above, to generate monomer building block type (37). Alternatively, may maleimide derivatives be prepared as described above and loaded onto SH-carrying oligonu-

cleotide's.

[0307] The transition metal catalyzed cross coupling is conducted as follows:

A premix of 1.4 mM Na_2PdCl_4 and 2.8 mM $\text{P}(\text{p-SO}_3\text{C}_6\text{H}_4)_3$ in water left for 15 min was added to a mixture of the template oligonucleotide (1 nmol) and monomer building block (36) and (37) (both 1 nmol) in 0.5 M NaOAc buffer at pH=5 and 75 mM NaCl (final $[\text{Pd}]=0.3$ mM). The mixture is then left o/n at 35-65 °C preferably 58°C, to yield template bound (38).

R = aryl, hetaryl or vinyl

F. Reactions of enamine and enolether monomer building blocks

[0308] Monomer building blocks loaded with enamines and enolethers may be prepared as follows:

For Z=NHR (R=H, alkyl, aryl, hetaryl), a 2-mercaptoethylamine may be reacted with a dipyridyl disulfide to generate the activated disulfide (40), which may then be condensed to a ketone or an aldehyde under dehydrating conditions to yield the enamine (41).

For Z=OH, 2-mercaptoethanol is reacted with a dipyridyl disulfide, followed by O-tosylation (Z=OTs). The tosylate (40) may then be reacted directly with an enolate or in the presence of fluoride with a O-trialkylsilylenolate to generate the enolate (41).

The enamine or enolate (41) may then be coupled onto an SH-carrying oligonucleotide as described above to give the monomer building block (42).

[0309] The monomer building blocks (42) may be reacted with a carbonyl carrying oligonucleotide like (44) or alternatively an alkylhalide carrying oligonucleotide like (43) as follows:

25 The template oligonucleotide (1 nmol) is mixed with monomer building block (42) (1 nmol) and (43) (1 nmol) in 50 mM MOPS, phosphate or hepes-buffer buffer and 250 mM NaCl solution, pH=7.5-8.5 and preferably pH=7.5. The reaction mixture is left at 35-65 °C preferably 58 °C over night or alternatively at a fluctuating temperature (10 °C for 1 second then 35 °C for 1 second) to yield template bound (46), where Z=O or NR. For compounds where Z=NR slightly acidic conditions may be applied to yield product (46) with Z=O.

30 The template oligonucleotide (1 nmol) is mixed with monomer building block (42) (1 nmol) and (44) (1 nmol) in 0.1 M TAPS, phosphate or hepes-buffer buffer and 300 mM NaCl solution, pH=7.5-8.5 and preferably pH=8.0. The reaction mixture is left at 35-65 °C preferably 58 °C over night or alternatively at a fluctuating temperature (10 °C for 1 second then 35 °C for 1 second) to yield template bound (45), where Z=O or NR. For compounds where Z=NR slightly acidic conditions may be applied to yield product (45) with Z=O.

[0310] Enolethers type (13) may undergo cycloaddition with or without catalysis. Similarly, may dienolethers be prepared and used. E.g. by reaction of (8) with the enolate or trialkylsilylenolate (in the presence of fluoride) of an α,β -unsaturated ketone or aldehyde to generate (47), which may be loaded onto an SH-carrying oligonucleotide, to yield monomer building block (48).

[0311] The diene (49), the ene (50) and the 1,3-dipole (51) may be formed by simple reaction between an amino carrying oligonucleotide and the NHS-ester of the corresponding organic building block. Reaction of (13) or alternatively (31, R"=vinyl) with dienes as e.g. (49) to yield (52) or e.g. 1,3-dipoles (51) to yield (53) and reaction of (48) or (31, R"=dienyl) with enes as e.g. (50) to yield (54) may be conducted as follows:

[0312] The template oligonucleotide (1 nmol) is mixed with monomer building block (13) or (48) (1 nmol) and (49) or (50) or (51) (1 nmol) in 50 mM MOPS, phosphate or hepes-buffer buffer and 2.8 M NaCl solution, pH=7.5-8.5 and preferably pH=7.5. The reaction mixture is left at 35-65 °C preferably 58 °C over night or alternatively at a fluctuating temperature (10 °C for 1 second then 35 °C for 1 second) to yield template bound (52), (53) or (54).

Linker cleavage

55 [0313] Activation (cleavage of some or all of the linkers connecting the complementing elements and the functional entity) may be done by changes in pH and/or temperature, addition of reactants or catalysts, enzymes or ribozymes, or light, UV or other electromagnetic radiation, etc. Particularly relevant enzymes include proteases, esterases and nucleases. A list of cleavable linkers and the conditions for cleavage is shown in (Figure 10).

[0314] Other cleavable linkers include the 4-hydroxymethyl phenoxyacetic acid moiety, which is cleaved by acid, the 2-[(tert-butyldiphenylsiloxy)methyl]benzoic acid moiety which is cleavable with fluoride, and the phosphate of a 2-hydroxymethyl benzoic acid moiety which provides a linker cleavable by the combination of alkaline phosphatase treatment followed by treatment with mild alkaline treatment.

[0315] In most cases, it is desirable to have at least two different types of linkers connecting the complementing elements with the functional entities. This way, it is possible to selectively cleave all but one of the linkers between the complementing template and the functional entities, thereby obtaining a polymer physically linked through just one linker to the template that templated its synthesis. This intact linker should affect the activities of the attached polymer as little as possible, but other than that, the nature of the linker is not considered an essential feature of this invention. The size of the linker in terms of the length between the template and the templated polymer can vary widely, but for the purposes of the invention, preferably the length is in the range from the length of just one bond, to a chain length of about 20 atoms.

Selection and screening of templated molecules

[0316] Selection or screening of the templated molecules with desired activities (for example binding to particular target, catalytic activity, or a particular effect in an activity assay) may be performed according to any standard protocol. For example, affinity selections may be performed according to the principles used for phage displayed, polysome-displayed or mRNA-protein fusion displayed peptides. Selection for catalytic activity may be performed by affinity selections on transition-state analog affinity columns (Baca et al., Proc. Natl. Acad. Sci. USA. 1997; 94(19):10063-8), or by function-based selection schemes (Pedersen et al., Proc. Natl. Acad. Sci. USA. 1998, 95(18):10523-8). Screening for a desired characteristic may be performed according to standard microtiter plate-based assays, or by FACS-sorting assays.

Use of libraries of templated molecules

Selection of template-displaying molecules that will bind to known targets

[0317] The present invention is also directed to approaches that allow selection of small molecules capable of binding to different targets. The template-displaying molecule technology contains a built-in function for direct selection and amplification. The binding of the selected molecule should be selective in that they only coordinate to a specific target and thereby prevent or induce a specific biological effect. Ultimately, these binding molecules should be possible to use e.g. as therapeutic agents, or as diagnostic agents.

[0318] Template-displaying molecule libraries can easily be combined with screenings, selections, or assays to assess the effect of binding of a molecule ligand on the function of the target. In a more specific embodiment, the template-displaying method provides a rapid means for isolating and identifying molecule ligands which bind to supra-molecular, macro-supra-molecular, macro-molecular and low-molecular structures (e.g. nucleic acids and proteins, including enzymes, receptors, antibodies, and glycoproteins); signal molecules (e.g. cAMP, inositol triphosphate, peptides, prostaglandins); and surfaces (e.g. metal, plastic, composite, glass, ceramics, rubber, skin, tissue).

[0319] Specifically, selection or partitioning in this context means any process whereby the template-displaying molecule complex bound to a target molecule, the complex-target pair, can be separated from template-displaying molecules not bound to the target molecule. Selection can be accomplished by various methods known in the art.

[0320] The selection strategy can be carried out so it allows selection against almost any target. Importantly, no steps in this selection strategy need any detailed structural information of the target or the molecules in the libraries. The entire process is driven by the binding affinity involved in the specific recognition/coordination of the molecules in the library to a given target. However, in some applications, if needed, functionality can also be included analogous to selection for catalytic activity using phage display (Soumilion et al. (1994) J. Mol. Biol. 237: 415-22; Pedersen et al. (1998) PNAS. 95: 10523-10528). Example of various selection procedures are described below.

[0321] This built-in template-displaying molecule selection process is well suited for optimizations, where the selection steps are made in series starting with the selection of binding molecules and ends with the optimized binding molecule. The single procedures in each step are possible to automate using various robotic systems. This is because there is a sequential flow of events and where each event can be performed separately. In a most preferable setting, a suitable template-displaying molecule library and the target molecule are supplied to a fully automatic system which finally generates the optimized binding molecule. Even more preferably, this process should run without any need of external work outside the robotic system during the entire procedure.

[0322] The libraries of template-displayed molecules will contain molecules that could potentially coordinate to any known or unknown target. The region of binding on a target could be into a catalytic site of an enzyme, a binding pocket on a receptor (e.g. GPCR), a protein surface area involved in protein-protein interaction (especially a hot-spot region), and a specific site on DNA (e.g. the major groove). The template-displaying molecule technology will primarily identify

molecules that coordinate to the target molecule. The natural function of the target could either be stimulated (agonized) or reduced (antagonized) or be unaffected by the binding of the template-displaying molecules. This will be dependent on the precise binding mode and the particular binding-site the template-displaying molecules occupy on the target. However, it is known that functional sites (e.g. protein-protein interaction or catalytic sites) on different proteins are more prone to bind molecules than other more neutral surface areas on a protein. In addition, these functional sites normally contain a smaller region that seems to be primarily responsible for the binding energy, the so called hot-spot regions (Wells, et al. (1993) Recent Prog. Hormone Res. 48; 253-262). This phenomenon will increase the possibility to directly select for small molecules that will affect the biological function of a certain target.

[0323] The template-displaying molecule technology of the invention will permit selection procedures analogous to other display methods such as phage display (Smith (1985) Science 228: 1315-1317). Phage display selection has been used successfully on peptides (Wells & Lowman. (1992) Curr. Op. Struct. Biol. 2, 597-604) proteins (Marks et al. (1992) J. Biol. Chem. 267: 16007-16010) and antibodies (Winter et al. (1994) Annu. Rev. Immunol. 12: 433-455). Similar selection procedures are also exploited for other types of display systems such as ribosome display (Mattheakis et al. (1994) Proc. Natl. Acad. Sci. 91: 9022-9026) and mRNA display (Roberts, et al. (1997) Proc. Natl. Acad. Sci. 94: 12297-302). However, the enclosed invention, the template-displaying molecule technology, will for the first time allow direct selection of target-specific small non-peptide molecules independently of the translation process on the ribosome complex. The necessary steps included in this invention are the amplification of the templates and incorporation and reaction of the monomer building blocks. The amplification and incorporation and the incorporation and reaction are either done in the same step or in a sequential process.

[0324] The linkage between the templated molecule (displayed molecule) and DNA replication unit (coding template) allows a rapid identification of binding molecules using various selection strategies. This invention allows a broad strategy in identifying binding molecules against any known target. In addition, this technology will also allow discovery of novel unknown targets by isolating binding molecules against unknown antigens (epitopes) and use these binding molecules for identification and validation (see section *"Target identification and validation"*).

[0325] As will be understood, selection of binding molecules from the template-displaying molecule libraries can be performed in any format to identify optimal binding molecules. A typical selection procedure against a purified target will include the following major steps: Generation of a template-displaying molecule library; Immobilization of the target molecule using a suitable immobilization approach; Adding the library to allow binding of the template-displayed molecules; Removing of the non-binding template-displayed molecules; Elution of the template-displayed molecules bound to the immobilized target; Amplification of enriched template-displaying molecules for identification by sequencing or to input for the next round of selection. The general steps are schematically shown in Figure 39.

[0326] In a preferred embodiment, a standard selection protocol using a template-displaying molecule library is to use the bio-panning method. In this technique, the target (e.g. protein or peptide conjugate) is immobilized onto a solid support and the template-displayed molecules that potentially coordinate to the target are the ones that are selected and enriched. However, the selection procedure requires that the bound template-displayed molecules can be separated from the unbound ones, i.e. those in solution. There are many ways in which this might be accomplished as known to ordinary skilled in the art.

[0327] The first step in the affinity enrichment cycle (one round as described in Figure 1) is when the template-displayed molecules showing low affinity for an immobilized target are washed away, leaving the strongly binding template-displayed molecules attached to the target. The enriched population, remaining bound to the target after the stringent washing, is then eluted with, e.g. acid, chaotropic salts, heat, competitive elution with the known ligand or proteolytic release of the target/template molecules. The eluted template-displayed molecules are suitable for PCR, leading to many orders of amplification, i.e. every single template-displayed molecule enriched in the first selection round participates in the further rounds of selection at a greatly increased copy number. After typically three to ten rounds of enrichment a population of molecules is obtained which is greatly enriched for the template-displayed molecules which bind most strongly to the target. This is followed quantitatively by assaying the proportion of template-displaying molecules which remain bound to the immobilized target. The variant template sequences are then individually sequenced.

[0328] Immobilisation of the target (peptide, protein, DNA or other antigen) on beads might be useful where there is doubt that the target will adsorb to the tube (e.g. unfolded targets eluted from SDS-PAGE gels). The derivatised beads can then be used to select from the template-displaying molecules, simply by sedimenting the beads in a bench centrifuge. Alternatively, the beads can be used to make an affinity column and the template-displaying libraries suspension recirculated through the column. There are many reactive matrices available for immobilizing the target molecule, including for instance attachment to $-NH_2$ groups and $-SH$ groups. Magnetic beads are essentially a variant on the above; the target is attached to magnetic beads which are then used in the selection. Activated beads are available with attachment sites for $-NH_2$ or $-COOH$ groups (which can be used for coupling). The target can be also be blotted onto nitrocellulose or PVDF. When using a blotting strategy, it is important to make sure the strip of blot used is blocked after immobilization of the target (e.g. with BSA or similar protein).

[0329] In another preferred embodiment, the selection or partitioning can also be performed using for example: Im-

munoprecipitation or indirect immunoprecipitation where the target molecule is captured together with template-displaying binding molecules; affinity column chromatography where the target is immobilized on a column and the template-displaying libraries are flowed through to capture target-binding molecules; gel-shift (agarose or polyacrylamide) where the selected template-displaying molecules migrate together with the target in the gel; FACS sorting to localize cells that coordinates template-displaying molecules; CsCl gradient centrifugation to isolate the target molecule together template-displaying binding molecules; Mass spectroscopy to identify target molecules which are labelled with template-displaying molecules; etc., without limitation. In general, any method where the template-displaying molecule/target complex can be separated from template-displaying molecules not bound to the target is useful.

Table 2: Examples of selection method possible to use to identify binding molecules using the template-displaying technology.

Type of Target	Method of choice
Soluble receptors	Direct immobilization, Immunoprecipitation, affinity column, FACS sorting, MS.
Cell surface receptor	Cell-surface subtraction selection, FACS sorting, Affinity column.
Enzyme inhibitors	Direct immobilization, Immunoprecipitation, affinity column, FACS sorting, MS.
Surface epitopes	Cell-surface subtraction selection, in-vivo selection, FACS sorting, Affinity column.

[0330] Elution of template-displayed molecules can be performed in different ways. The binding molecules can be released from the target molecule by denaturation, acid, or chaotropic salts and then transferred to another vial for amplification. Alternatively, the elution can be more specific to reduce the background. Elution can be accomplished using proteolysis to cleave a linker between the target and the immobilizing surface or between the displaying molecule and the template. Also, elution can be accomplished by competition with a known ligand. Alternatively, the PCR reaction can be performed directly in the washed wells at the end of the selection reaction.

[0331] A possible feature of the invention is the fact that the binding molecules need not be elutable from the target to be selectable since only the encoding template DNA is needed for further amplification or cloning, not the binding molecule itself. It is known that some selection procedure can bind the most avid ligands so tightly as to be very difficult to elute. However the method of the invention can successfully be practiced to yield avid ligands, even covalent binding ligands.

[0332] Alternative selection protocol includes a known ligand as fragment of each displayed molecule in the library. That known ligand will guide the selection by coordinate to a defined part on the target molecule and focus the selection to molecules that binds to the same region. This could be especially useful for increasing the affinity for a ligand with a desired biological function but with a too low potency.

[0333] A further aspect of the present invention relates to methods of increasing the diversity or complexity of a single or a mixture of selected binding molecules. After the initial selection, the enriched molecules can be altered to further increase the chemical diversity or complexity of the displayed molecules. This can be performed using various methods known to the art. For example, using synthesized randomized oligonucleotides, spiked oligonucleotides or random mutagenesis. The randomization can be focused to allow preferable codons or localized to a predetermined portion or sub-sequence of the template nucleotide sequence. Other preferable method is to recombine templates coding for the binding molecules in a similar manner as DNA shuffling is used on homologous genes for proteins (Stemmer (1994) Nature 370:389-91). This approach can be used to recombine initial libraries or more preferably to recombine enriched encoding templates.

[0334] In another embodiment of the invention when binding molecules against specific antigens that is only possible to express on a cell surface, e.g. ion channels or transmembrane receptors, is required, the cells particle themselves can be used as the selection agent. In this sort of approach, cells lacking the specific target should be used to do one or more rounds of negative selection or be present in large excess in the selection process. Here, irrelevant template-displayed molecules are removed. For example, for a positive selection against a receptor expressed on whole cells, the negative selection would be against the untransformed cells. This approach is also called subtraction selection and has successfully been used for phage display on antibody libraries (Hoogenboom et al. (1998) Immunotech. 4: 1-20). A specific example of a selection procedure can involve selection against cell surface receptors that become internalized from the membrane so that the receptor together with the selected binding molecule can make its way into the cell cytoplasm or cell nucleus. Depending on the dissociation rate constant for specific selected binding molecules, these molecules largely reside after uptake in either the cytoplasm or the nucleus.

[0335] The skilled person in the art will acknowledge that the selection process can be performed in any setup where the target is used as the bait onto which the template-displaying molecules can coordinate.

[0336] The selection methods of the present invention can be combined with secondary selection or screening to identify molecule ligands capable of modifying target molecule function upon binding. Thus, the methods described herein can be employed to isolate or produce binding molecules which bind to and modify the function of any protein or nucleic acid. It is contemplated that the method of the present invention can be employed to identify, isolate or produce binding molecules which will affect catalytic activity of target enzymes, *i.e.*, inhibit catalysis or modifying substrate binding, affect the functionality of protein receptors, *i.e.*, inhibit binding to receptors or modify the specificity of binding to receptors; affect the formation of protein multimers, *i.e.*, disrupt quaternary structure of protein subunits; and modify transport properties of protein, *i.e.*, disrupt transport of small molecules or ions by proteins.

[0337] A still further aspect of the present invention relates to methods allowing functionality in the selection process can also be included. For example, when enrichment against a certain target have been performed generation a number of different hits, these hits can then directly be tested for functionality (e.g. cell signalling). This can for example be performed using fluorescence-activated cell sorting (FACS).

[0338] The altered phenotype may be detected in a wide variety of ways. Generally, the changed phenotype is detected using, for example: microscopic analysis of cell morphology; standard cell viability assays, including both increased cell death and increased cell viability; standard labelling assays such as fluorometric indicator assays for the presence of level of particular cell or molecule, including FACS or other dye staining techniques; biochemical detection of the expression of target compounds after killing the cells; etc. In some cases, specific signalling pathways can be probed using various reporter gene constructs.

[0339] Secondary selection methods that can be combined with template-displaying molecule technology include among others selections or screens for enzyme inhibition, alteration or substrate binding, loss of functionality, disruption of structure, etc. Those of ordinary skill in the art are able to select among various alternatives of selection or screening methods that are compatible with the methods described herein.

[0340] The binding molecules of the invention can be selected for other properties in addition to binding. For example, during selection; stability to certain conditions of the desired working environment of the end product can be included as a selection criterion. If binding molecules which are stable in the presence of a certain protease is desired, that protease can be part of the buffer medium used during selection. Similarly, the selection can also be performed in serum or cell extracts or any type of media. As will be understood, when utilizing this template-displaying approach, conditions which disrupt or degrade the template should be avoided to allow amplification. Other desired properties can be incorporated, directly into the displaying molecules as will be understood by those skilled in the art. For example, membrane affinity can be included as a property by employing building blocks with high hydrophobicity.

[0341] Molecules selected by the template-displaying molecule technology can be produced by various synthetic methods. Chemical synthesis can be accomplished since the structure of selected binding molecules is readily obtained from the nucleic acid sequence of the coding template. Chemical synthesis of the selected molecules is also possible because the building blocks that compose the binding molecules are also known in addition to the chemical reactions that assemble them together.

[0342] In a preferred embodiment, the selected binding molecules is synthesized and tested in various appropriate *in vitro* and *in vivo* testing to verify the selected candidates for biological effects and potency. This may be done in a variety of ways, as will be appreciated by those in the art, and may depend on the composition of the bioactive molecule.

Target identification and validation

[0343] In another aspect, the present invention provides methods to identify or isolate targets that are involved in pathological processes or other biological events. In this aspect, the target molecules are again preferably proteins or nucleic acids, but can also include, among others, carbohydrates and various molecules to which specific molecule ligand binding can be achieved. In principal, the template-displaying molecule technology could be used to select for specific epitopes on antigens found on cells, tissues or *in vivo*. These epitopes might belong to a target that is involved in important biological events. In addition, these epitopes might also be involved in the biological function of the target.

[0344] Phage display with antibodies and peptide libraries has been used numerous times successfully in identifying new cellular antigens. (e.g. Pasqualini et al. (1996) Nature 380: 364-366; Pasqualini et al. (2000) Cancer Res. 60: 722-727; Scheffer et al. (2002) Br J Cancer 86: 954-962; Kupsch et al. (1999) Clin Cancer Res. 5: 925-931; Tseng-Law et al. (1999) Exp. Hematol. 27: 936-945; Gevorkian et al. (1998) Clin. Immunol. Immunopathol. 86: 305-309). Especially effective have been selection directly on cells suspected to express cell-specific antigens. Importantly, when selecting for cell-surface antigen, the template molecule can be maintained outside the cell. This will increase the probability that the template molecule will be intact after release for the cell surface.

[0345] *In vivo* selection of template-displayed molecules has tremendous potential. By selecting from libraries of template-displayed molecules *in vivo* it is possible to isolate molecules capable of homing specifically to normal tissues

and other pathological tissues (e.g. tumours). This principle has been illustrated using phage display of peptide libraries (Pasqualini & Ruoslahti (1996) Nature 280: 364-366). This system has also been used in humans to identify peptide motifs that localized to different organs (Arap et al. (2002) Nat. Med. 2:121-127). A similar selection procedure could be used for the template-displaying libraries. The coding DNA in phage display is protected effectively by the phage particle allows selection *in vivo*. Accordingly, the stability of the template *in vivo* will be important for amplification and identification. The template can be stabilised using various nucleotide derivatives in a similar way as have been used to stabilise aptamers for *in vivo* applications (Nolte (1996) Nature Biotechnol. 14: 1116-1121; Pagratis et al. (1997) Nature Biotechnol. 15: 68-72). However, it is reasonable to believe that the template structure will be stabilized against degradation due to the modified bases used for encoding the displayed molecule. Other types of protection are also possible where the template molecule is shielded for the solution using various methods. This could include for example liposomes, pegylation, binding proteins or other sorts of protection. The template molecule could also be integrated into another designed structure that protects the template from external manipulation. For example, the linker can be design to be incorporated in vesicles to position the templates inside the vesicle and the displaying molecules on the outside. The arrangement will protect the template molecules from external manipulate and at the same time allow exposure of the displaying molecules to permit selection.

[0346] Most antibodies have a large concave binding area which requires to some degree protruding epitopes on the antigens. Also, the antibody molecule is a large macromolecule (150 KDa) which will sterically reduce the access for a number of different antigens (e.g. on a cell surface). The template-displaying technology should be able to access and recognize epitopes inaccessible to antibodies. The small binding molecules will be able to bind into active sites, grooves and other areas on an antigen. The coding template element is also smaller than an antibody which will increase the physical access of the template-binding molecule pair. In addition, the diversity and complexity of the template-displaying molecule libraries will be much greater compared to peptide libraries. This will increase the possibility to find molecules that can coordinate to epitopes inaccessible to peptides due to inadequate chemistry. All together, the template-displaying molecule technology has the potential to identify novel antigens which is not possible to identify with antibodies or peptides. One of ordinary skill in the art will acknowledge that various types of cells can be used in the selection procedure. It will also be understood that the selection for new antigens can be performed using subtraction methods as described previously.

[0347] Another aspect of the present invention relates to methods to validate the identified target. The identified binding molecules can directly be used if they change the biological response of the target. This can be done either *in vitro* using any direct or cell-based assay or directly *in vivo* studying any phenotypic response. The strength of this approach is that the same molecules are used both for identification and validation of various targets. Most favourable, the binding molecules could also directly be used as therapeutic agents.

[0348] In another preferred embodiment, the template-displaying molecules are used to pull out the target molecules. This can for instance be achieved by selection against a cDNA library expressed on bacteriophage (libraries vs. libraries). By mixing a template-displaying molecule library with a cDNA library it will be possible to find binding pairs between the small molecules in the template-displaying molecule library and proteins from the cDNA library. One possibility is to mix a phage display library with a template display library and do a selection for either the phage or template library. The selected library is then plated to localized phage clones and the DNA coding for the phage and template displayed molecules can then be identified using PCR. Other types of libraries than cDNA could also be used such as nucleic acids, carbohydrates, synthetic polymer.

[0349] In another embodiment of the invention the template-displaying molecule technology can be used to account for *in vivo* and *in vitro* drug metabolism. That could include both phase I (activation) and phase II (detoxification) reactions. The major classes of reactions are oxidation, reduction, and hydrolysis. Other enzymes catalyze conjugations. These enzymes could be used as targets in a selection process to eliminate displayed molecule that are prone to coordinate to these enzymes. The templates corresponding to these displayed molecules could subsequently be used to compete or eliminate these molecules when making template-displaying molecule libraries.

[0350] These obtained libraries will then be free of molecules that will have a tendency of binding to enzymes involved in phase I-II and possibly be faster eliminated. For instance, a selection on each separate enzyme or any combination of cytochrome P450 enzymes, flavin monooxygenase, monoamine oxidase, esterases, amidases, hydrolases, reductases, dehydrogenases, oxidases UDP-glucuronosyltransferases, glutathione S-transferases as well as other relevant enzymes could be performed to identify these binding molecules that are prone to coordinate to these metabolic enzymes. Inhibitors are easily selected for due to their binding affinity but substrates need at least micro molar affinity to be identified.

[0351] Another interesting embodiment of this invention is the possibility to directly select for molecules that passively or actively becomes transported across epithelial plasma membrane, or other membranes. One possible selection assay is to use CaCO-2 cells, a human colon epithelial cell line, which is general, accepted as a good model for the epithelial barrier in the gastrointestinal guts. The CaCO-2 assay involves growing a human colon epithelial cell line on tissue culture well inserts, such that the resultant monolayer forms a biological barrier between apical and basolateral compartments. The template-displaying molecule libraries are placed either side of the cell monolayer and the molecules

that can permeate the cell monolayer is collected and amplified. This process can be repeated until active molecules have been identified. Other cell line or setup of this assay is possible and is obvious for skill in the art.

[0352] A still further aspect of the present invention relates methods of selecting for stability of the selected molecules. This could be performed by subjecting an enriched pool of binding molecules to an environment that will possibly degrade or change the structure of the binding molecules. Various conditions could be certain proteases or a mixture of protease, cell extract, and various fluids from for example the gastrointestinal gut. Other conditions could be various salts or acid milieu or elevated temperature. Another possibility is to generate a library of known ligands and subject that library to stability tests and selection to identify stable molecules under certain conditions as describe above.

Therapeutic applications

[0353] The potential therapeutic applications of the invention are great. For example, the template-displaying molecule technology of the invention may be used for blocking or stimulating various targets. A therapeutically relevant target is a substance that is known or suspected to be involved in a regulating process that is malfunctioning and thus leads to a disease state. Examples of such processes are receptor-ligand interaction, transcription-DNA interaction, and cell-cell interaction involving adhesion molecules, cofactor-enzyme interaction, and protein-protein interaction in intracellular signalling. Target molecule means any compound of interest for which a molecule ligand is desired. Thus, target can, for example, include a chemical compound, a mixture of chemical compounds, an array of spatially localized compounds, a biological macromolecule, such as DNA or mRNA, a bacteriophage peptide display library, a ribosome peptide display library, an extract made from biological materials such as bacteria, plants, fungi, or animal (e.g. mammalian) cells or tissue, protein, fusion protein, peptide, enzyme, receptor, receptor ligand, hormone, antigen, antibody, drug, dye, growth factor, lipid, substrate, toxin, virus, or the like etc., without limitation. Other examples of targets include, e.g. a whole cell, a whole tissue, a mixture of related or unrelated proteins, a mixture of viruses or bacterial strains or the like. etc., without limitation.

[0354] Therapeutic drug targets can be divided into different classes according to function; receptors, enzymes, hormones, transcription factors, ion channels, nuclear receptors, DNA, (Drews, J. (2000) Science 287:1960-1964). Among those, receptors, nuclear receptors, and metabolic enzymes constitute overwhelmingly the majority of known targets for existing drugs. Especially, G Protein-Coupled Receptors (GPCR) constitutes one of the most important classes of drug targets together with proteases for pharmacological intervention. Although the above examples are focused on the most relevant targets, it will be self-evident for a person skilled in the art that any other therapeutic target may be of interest.

[0355] The present invention employing the template-displaying molecule technology can be utilized to identify agonists or antagonists for all these classes of drug targets, dependent on the specific properties each target holds. Most of the targets are possible to obtain in a purified form for direct selection procedures. Other targets have to be used when they are in their native environments such as imbedded cell surface receptors. In those situations the selection using the template-displaying molecule libraries can be performed using subtraction-selection described previously.

[0356] One specific application of the template-displaying molecule technology of the invention is to generate molecules that can function as antagonists, where the molecules block the interaction between a receptor and one or more ligands. Another application includes cell targeting. For example, the generated molecules recognizing specific surface proteins or receptors will be able to bind to certain cell types. Such molecules may in addition carry another therapeutic agent to increase the potency and reduce the side-effects (for example cancer treatment). Applications involving antiviral agents are also included. For example, a generated molecule, which binds strongly to epitopes on the virus particle, may be useful as an antiviral agent. Another specific application of the template-displaying molecule technology of the invention is to generate molecules that can function as agonists, where the molecules stimulate or activate a receptor to initiate a cellular signalling pathway.

Template-displaying molecule arrays

[0357] A still further aspect of the present invention relates to methods for detecting the presence or absence of, and /or measuring the amount of target molecules in a sample, which employs a molecule ligand which can be isolated by the methods described herein. These molecule ligands can be used separately or in array system for multiple determinations.

[0358] An understanding of protein structures, protein-to-protein interactions, pathways and how proteins influence the origins of disease is of vital importance. Nucleic acid microarrays have enabled researchers to pursue novel biomarkers through genotyping. However, a major hurdle is the lack of correlation between gene expression at the level of mRNA level and the amount of corresponding protein expressed within the cell (Andersson et al. (1997) Electrophoresis 18: 533-537). Contrary to DNA and RNA analysis, the use of biochips for parallel protein function studies has been much more difficult. Unlike hybridization reactions, which are based on couplings or interactions of linear sequences, the protein interactions involve polypeptide surfaces arising from 3D folded amino-acid sequences. The requirement for

preparation of 3D folded proteins substantially complicates fabrication of protein microarrays. The protein microarrays would be very sensitive to and can be easily degraded by the use of thermal treatments and harsh chemicals. Moreover, the folded protein interactions have a much stronger dependency on sequences compared to the hybridization reactions used on the DNA/RNA biochips. The sequence dependency of the protein interactions will further complicate the reaction kinetics.

[0359] The invention described herein provides a possible solution to making arrays that can measure different amounts at the protein level without the use of proteins or peptides as detection molecules. The template-displaying molecule technology could be used to identify small binding molecules to numerous targets. These binding molecules could then be arrayed in specific positions and work as detection molecule to measure the amount of various biomarkers. For example, binding molecule against cytokines or enzymes known to be involved in a specific pathway could be generate with the describe technology. These binding molecules could then be spotted in an array format to be used to measure the absolute or relative amount of each cytokine or enzyme.

[0360] One major advantage with this system is that the spotting technology used for DNA arrays could be identically applied for this system. The template-displayed molecules could be directly applied to the spotted DNA. Another possibility is that the synthesis could be performed directly on the pre-coated template using a polymerase and the nucleotide analogues. Make addressable microarrays with this technology will lead to high-throughput deposition of thousands of different functional molecules onto different locations of a chip. The overall principal is shown in figure 40.

[0361] The template-displaying molecule technology is not limited in chemistry to the 20 natural occurring amino acids. This will permit synthesis on the template of more robust and stable molecules that will bind to various targets. These more stable molecules will be more suitable to become immobilized on a surface and exposed to any harsh conditions such as heat, low or high pH various detergent. In addition, the shelf-life of the arrays will be much longer that arrays made from proteins.

Molecular biological tools

[0362] Polymerase chain reaction (PCR) is an exemplary method for amplifying nucleic acids. Descriptions of PCR methods are found (Saiki et al. (1985) Science 230: 1350-1354; Scharf et al. (1986) Science 233: 1076-1078; U.S Patent 4,683,202 (Mullis et al.)). Alternative methods of amplification include among others cloning of selected DNAs into appropriate vector and introduction of that vector into a host organism where the vector and the cloned DNAs are replicated and thus amplified (Guatelli et al. (1990) Proc. Natl. Acad. Sci. 87: 1874-1878). In general, any means that will allow faithful, efficient amplification of selected nucleic acid sequences can be employed in the method of the present invention. It is only necessary that the proportionate representations of the sequences after amplification reflect the relative proportions of sequences in the mixture before amplification.

[0363] The template variants of the present invention may be produced by any suitable method known in the art. Such methods include constructing a nucleotide sequence by chemical synthesis or a combination of chemical synthesis and recombinant DNA technology.

[0364] A nucleotide sequence encoding a template variant of the invention may be constructed by isolating or synthesizing a nucleotide sequence encoding the appropriate display molecules and then changing the nucleotide sequence so as to effect introduction (i.e. insertion or substitution) or removal (i.e. deletion or substitution) of the relevant functional entities of the displayed molecules.

[0365] The nucleotide sequence corresponding to the template molecules is conveniently modified by site-directed mutagenesis in accordance with conventional methods. Alternatively, the nucleotide sequence is prepared by chemical synthesis, e.g. by using an oligonucleotide synthesizer, wherein oligonucleotides are designed based on the sequence of the desired templates. For example, small oligonucleotides coding for portions of the desired template may be synthesized and assembled by PCR, ligation or ligation chain reaction (LCR) (Barany, PNAS 88:189-193, 1991). The individual oligonucleotides typically contain 5' or 3' overhangs for complementary assembly.

[0366] Alternative nucleotide sequence modification methods are available for producing template variants for high throughput screening or selection. For instance, methods which involve homologous cross-over such as disclosed in US 5,093,257, and methods which involve gene shuffling, i.e. recombination between two or more homologous nucleotide sequences resulting in new nucleotide sequences having a number of nucleotide alterations when compared to the starting nucleotide sequences. Gene shuffling (also known as DNA shuffling) involves one or more cycles of random fragmentation and reassembly of the nucleotide sequences, followed by selection to select nucleotide template sequences encoding variant displaying molecules with the desired properties.

[0367] Examples of suitable *in vitro* gene shuffling methods are disclosed by Stemmer et al. (1994), Proc. Natl. Acad. Sci. USA; vol. 91, pp. 10747-10751; Stemmer (1994), Nature, vol. 370, pp. 389-391; Smith (1994), Nature vol. 370, pp. 324-325; Zhao et al., Nat. Biotechnol. 1998, Mar; 16(3): 258-61; Zhao H. and Arnold, FB, Nucleic Acids Research, 1997, Vol. 25. No. 6 pp. 1307-1308; Shao et al., Nucleic Acids Research 1998, Jan 15; 26(2): pp. 681-83; and WO 95/17413.

[0368] Synthetic shuffling involves providing libraries of overlapping synthetic oligonucleotides based e.g. on a flanking

sequence. The synthetically generated oligonucleotides are recombined, and the resulting recombinant nucleic acid sequences are screened and if desired used for further shuffling cycles.

[0369] Recombination can be theoretically calculated, which is performed or modelled using a computer system, thereby partly or entirely avoiding the need for physically manipulating nucleic acids.

[0370] Once assembled (by synthesis, site-directed mutagenesis, DNA shuffling or another method), the nucleotide sequence encoding the templates is used to generate the template-displaying libraries.

[0371] Still other aspects of the present invention relates to a pharmaceutical composition comprising the conjugate or the variant of the invention as well as to methods of producing and using the conjugates and variants of the invention.

[0372] The term "affinity" is used herein as a qualitative term to describe the molecule/target interaction. A quantitative measure for the affinity is expressed through the Association Constant (K_A). The Association Constant and the Dissociation Constant is related to each other by the equation $K_D = 1/K_A$. Evidently, a high affinity corresponds to a lower Dissociation Constant. The term "binds to a specific target" means that the binding molecules obtained with the template-displaying molecule technology binds to a chosen target so that a measurable response is obtained when tested in a suitable binding or functional assay. In the present context, the term "therapeutic agent" is intended to mean any biologically or pharmacologically active substance or antigen-comprising material; the term includes substances which have utility in the treatment or prevention of diseases or disorders affecting animals and humans, or in the regulation of any animal or human physiological condition and it also includes any biological active compound or composition which, when administrated in an effective amount, has an effect on living cells or organisms.

[0373] After the construction of template-displayed libraries, template-displaying molecules bearing the desired ligands can be captured using the below protocol. Coat two wells of two flat-bottom microtiter plates with about 1 μ g streptavidin in a TBS buffer. Incubate over night at 4 °C. Remove the streptavidin solution and wash the wells at least six times with TBS. Immediately add 2% BSA to block the wells and incubate for about 30 min. at 37 °C. Wash the plate with TBS buffer at least three times. Add about 0.1 μ g biotinylated target molecule (biotinylation can be performed as described in the literature) to one of the wells (use the other as background control) and incubate for about 30 min at 20 °C and then remove the excess by washing with TBS buffer at least six times. Block free streptavidin molecules with 1 mM biotin for 5 min. and wash excess away with TBS buffer at least six times. Add then the template-displaying molecule library to both wells and allow binding by incubating at 20 °C for about 1 hour. Wash the wells with TBS buffer at least six times to remove template-displaying molecules that not coordinate to the immobilized target molecule. Elute the coordinated template-displaying molecules using condition that remove the binding molecules. In later selection cycles, compare the number of eluted molecules between the wells with and without the target molecule to make sure there are more template-displaying molecules eluted in the well with target. That will ensure that there is a specific enrichment in the selection process. Other types and numerous variations of selection procedures can be found in the literature (e.g. "Phage display: A laboratory manual" (2001) Barbas et al., Eds. Cold Spring Harbor Laboratory Press, New York).

[0374] An alternative to the above capturing is, after the construction of template-displayed libraries, to capture the template-displaying molecules bearing the desired ligands using the below protocol. The selection of template-display molecules can be performed using magnetically activated cell sorting (Siegel et al. (1997) J. Immunol. Methods 206: 73-85). Positive cells (cells with the antigen of interest) is cell-surface biotinylated using sulfo-NHS-LC-biotin (Pierce). Add approximately 10^6 biotinylated cells to 10 μ l streptavidin-coated paramagnetic microbeads (Dyna) and allow binding. Add about 10^8 negative cells (cells without the antigen of interest). These negative cells act as a sink for nonspecific template-displaying molecules, and the target cells capture the specific template-displaying molecules. Pellet the cell mixture, discard the supernatant, and suspend in the template-displaying library suspension. Incubate about 2 hours at 37 °C on a rotator to keep the cells in suspension. Load the cell/template-displaying library solution on a magnetic column to recover the positive cells by wash off all the negative cells. Finally elute the positive cells by removing the magnetic field and amplify the eluted templates using PCR. This selection protocol can be repeated several times if needed.

Amplification of templates capable of templating the synthesis of templated molecules

[0375] In one aspect the present invention relates to methods for amplifying templated molecules that may or may not be bound to a target. The choice of amplification method depends on the choice of coding or complementing elements. Natural oligonucleotides can be amplified by any state of the art method. These methods include, but is not limited to the polymerase chain reaction (PCR); as well as e.g. nucleic acid sequence-based amplification (e.g. Compton, Nature 350, 91-92 (1991)), amplified anti-sense RNA (e.g. van Gelder et al., PNAS 85: 77652-77656 (1988)); self-sustained sequence replication system (e.g. Gnatelli et al., PNAS 87: 1874-1878 (1990)); polymerase independent amplification as described in e.g. Schmidt et al., NAR 25: 4797-4802 (1997), as well as in vivo amplification of plasmids carrying cloned DNA fragments. Ligase-mediated amplification methods may also be used, e.g., LCR (Ligase Chain Reaction).

[0376] For non-natural nucleotides the choices of efficient amplification procedures are fewer. As non-natural nucleotides per definition can be incorporated by certain enzymes including polymerases, it will be possible to perform manual polymerase chain reaction by adding the polymerase during each extension cycle.

[0377] For oligonucleotides containing nucleotide analogs, fewer methods for amplification exist. One may use non-enzyme mediated amplification schemes (Schmidt et al., NAR 25: 4797-4802 (1997)). For backbone-modified oligonucleotide analogs such as PNA and LNA, this amplification method may be used. Before or during amplification the templates or complementing templates may be mutagenized or recombined in order to create a larger diversity for the next round of selection or screening.

Characterization of polymers isolated by the selections or screening assays.

[0378] After the final round of selection, it is often desirable to sequence individual templates, in order to determine the sequence of individual templated polymers. If the template contains natural nucleotides, it is a standard routine to optionally PCR amplify the isolated templates (if the template is an RNA molecule, it is necessary to use reverse transcriptase to produce cDNA prior to the PCR-amplification), and then clone the DNA fragments into for example plasmids, transform these and then sequence individual plasmid-clones containing one or multiple tandem DNA sequences. In this case, it is practical to design a restriction site in both of the flanking sequences to the central random or partly random sequence of the template (i.e., in the primer binding sites). This will allow easy cloning of the isolated nucleotides. Sequencing can be done by the standard dideoxy chain termination method, or by more classical means such as Maxam-Gilbert sequencing.

[0379] If the template contains non-natural nucleotides, it is not feasible to clone individual sequences by transfer through a microbial host. However, using bead populations where each bead carries one oligonucleotide sequence, it is possible to clone in vitro, whereafter all the nucleotides attached to a specific bead may be optionally amplified and then sequenced (Brenner et al., 2000, Proc. Natl. Acad. Sci. USA 97, 1665-1670). Alternatively, one may dilute the population of isolates adequately, and then aliquot into microtiter plates so that the wells on average contain for example 0.1 templates. By amplifying the single templates by for example PCR, it will now be possible to sequence using standard methods. Of course, this requires that the non-natural nucleotides are substrates for the thermostable polymerase used in the PCR.

[0380] If alternative methods are used that require shorter oligonucleotides it may be desirable to design the starting template so as to contain restriction sites on either side of the encoding/templating region of the template. Thereby, after the final selection round, the templates can be restricted, to obtain a short oligonucleotide encoding the templated polymer, and then these short oligos can be applied to various analytical procedures.

[0381] It is also possible to sequence the isolates by the use of a DNA array of oligos with random but predetermined sequences.

[0382] It may also be desirable to sequence the population of isolates as a pool, for example if the sequences are expected to be in register, for example because the initial library consisted of a degenerate sequence based on a polymer sequence with a known (relatively high) desired activity. Therefore, it is then expected that all the isolates have sequences similar to the initial sequence of the templates before selection. Wherefore the population of isolates can be sequenced as a whole, to obtain a consensus sequence for the population as a whole.

Templated molecules

[0383] A non-exhaustive and non-limiting list of oligomers that may be templated by the various principles described in the present invention is listed below:

- alpha-, beta-, gamma-, and omega-peptides
- mono-, di- and tri-substituted peptides
- L- and D-form peptides
- cyclohexane- and cyclopentane-backbone modified beta-peptides
- vinyllogous polypeptides
- glycopolypeptides
- polyamides
- vinyllogous sulfonamide peptide
- Polysulfonamide
- conjugated peptide (i.e., having prosthetic groups)
- Polyesters
- Polysaccharides
- Polycarbamates
- Polycarbonates
- Polyureas
- poly-peptidylphosphonates

Azatides
 peptoids (oligo N-substituted glycines)
 Polyethers
 ethoxyformacetal oligomers
 5 poly-thioethers
 polyethylene glycols (PEG)
 Polyethylenes
 Polydisulfides
 polyarylene sulfides
 10 Polynucleotides
 PNAs
 LNAs
 Morpholinos
 oligo pyrrolinone
 15 polyoximes
 Polyimines
 Polyethyleneimine
 Polyacetates
 Polystyrenes
 20 Polyacetylene
 Polyvinyl
 Lipids
 Phospholipids
 Glycolipids
 25 polycycles (aliphatic)
 polycycles (aromatic)
 polyheterocycles
 Proteoglycan
 Polysiloxanes
 30 Polyisocyanides
 Polyisocyanates
 Polymethacrylates
 Monofunctional, Difunctional, Trifunctional and Oligofunctional open-chain hydrocarbons.
 Monofunctional, Difunctional, Trifunctional and Oligofunctional Nonaromatic Carbocycles.
 35 Monocyclic, Bicyclic, Tricyclic and Polycyclic Hydrocarbons
 Bridged Polycyclic Hydrocarbones
 Monofunctional, Difunctional, Trifunctional and Oligofunctional Nonaromatic Heterocycles.
 Monocyclic, Bicyclic, Tricyclic and Polycyclic Heterocycles
 Bridged Polycyclic Heterocycles
 40 Monofunctional, Difunctional, Trifunctional and Oligofunctional Aromatic Carbocycles.
 Monocyclic, Bicyclic, Tricyclic and Polycyclic Aromatic Carbocycles
 Monofunctional, Difunctional, Trifunctional and Oligofunctional Aromatic Heterocycles.
 Monocyclic, Bicyclic, Tricyclic and Polycyclic Heterocycles
 Chelates
 45 Fullerenes.
 Any combination of the above.

[0384] The list refers to any linear, branched or cyclic structure that contains one or more of the backbone structures listed, and/or contain several bonds of the same kind (e.g. amide bonds). Heteropolymers (hybrids of different polymer types) can also be templated by the present invention.

[0385] Below a table is presented stating the polymers producible according to the present invention as well as the functional entities/reactive groups required to make them. A reference is made to the relevant figure:

Polymer	Functional Entity (reactive groups)	Linking molecule	Catalyst/reagent	General Figure	Specific Figure
polycyclic compound	bi-coumanin		light	Fig. 11	Fig. 11, ex. 1
polyester	alcohol carboxylic acid		carbodiimide	Fig. 12, Fig. 21	
polyester	hydroxyl, thioester			Fig. 14	
polyurea	di-amine	carbonyl/dimidazole		Fig. 15	Fig. 15, ex. 3
polyacetate	halogen, carboxylic acid		base	Fig. 12, Fig. 22	
polyacetate	alcohol, carboxylic acid		EDC or other carbodiimide	Fig. 12, Fig. 22	
polycarbonate	alcohol, isocyanate			Fig. 12, Fig. 22	
polycarbonate	diol	carbonyl/dimidazole		Fig. 15	
peptoid	secondary amine, or haloacetyl			Fig. 12, Fig. 22	
	primary amine, or haloacetyl		alkylating agent	Fig. 12, Fig. 22	
glycogen	UDP-glucose		glycogen synthetase	Fig. 12, Fig. 22	
polysaccharide	UDP-activated saccharides		polysaccharide synthetases	Fig. 12, Fig. 22	
polysaccharide	glucosyl sulphide/sulfoxide activation system (Kahne glucosylation)		Kahne conditions	Fig. 12, Fig. 22	
polyamide	amine N-hydroxysuccinimide ester			Fig. 12, Fig. 22	
polyamide	amine, carboxylic acid		carbodiimide	Fig. 12, Fig. 22

Templates

[0386] In one embodiment, the templated molecule is linked by means of a single linker to the complementing template or template that templated the synthesis of the templated molecule. In another embodiment, the method for templating a templated molecule comprises the further step of releasing the template or complementing template that templated the templated molecule, and obtaining a templated molecule that is not linked to the complementing template or template that templated the synthesis of the templated molecule.

[0387] The template preferably comprises n coding elements in a linear sequence. The template comprising n coding elements can also be branched. n preferably has a value of from 2 to 200, for example from 2 to 100, such as from 2 to 80, for example from 2 to 60, such as from 2 to 40, for example from 2 to 30, such as from 2 to 20, for example from 2 to 15, such as from 2 to 10, such as from 2 to 8, for example from 2 to 6, such as from 2 to 4, for example 2, such as from 3 to 100, for example from 3 to 80, such as from 3 to 60, such as from 3 to 40, for example from 3 to 30, such as from 3 to 20, such as from 3 to 15, for example from 3 to 15, such as from 3 to 10, such as from 3 to 8, for example from 3 to 6, such as from 3 to 4, for example 3, such as from 4 to 100, for example from 4 to 80, such as from 4 to 60, such as from 4 to 40, for example from 4 to 30, such as from 4 to 20, such as from 4 to 15, for example from 4 to 10, such as from 4 to 8, such as from 4 to 6, for example 4, for example from 5 to 100, such as from 5 to 80, for example from 5 to 60, such as from 5 to 40, for example from 5 to 30, such as from 5 to 20, for example from 5 to 15, such as from 5 to 10, such as from 5 to 8, for example from 5 to 6, for example 5, such as from 6 to 100, for example from 6 to 80, such as from 6 to 60, such as from 6 to 40, for example from 6 to 30, such as from 6 to 20, such as from 6 to 15, for example from 6 to 10, such as from 6 to 8, such as 6, for example from 7 to 100, such as from 7 to 80, for example from 7 to 60, such as from 7 to 40, for example from 7 to 30, such as from 7 to 20, for example from 7 to 15, such as from 7 to 10, such as from 7 to 8, for example 7, for example from 8 to 100, such as from 8 to 80, for example from 8 to 60, such as from 8 to 40, for example from 8 to 30, such as from 8 to 20, for example from 8 to 15, such as from 8 to 10, such as 8, for example 9, for example from 10 to 100, such as from 10 to 80, for example from 10 to 60, such as from 10 to 40, for example from 10 to 30, such as from 10 to 20, for example from 10 to 15, such as from 10 to 12, such as 10, for example from 12 to 100, such as from 12 to 80, for example from 12 to 60, such as from 12 to 40, for example from 12 to 30, such as from 12 to 20, for example from 12 to 15, such as from 14 to 100, such as from 14 to 80, for example from 14 to 60, such as from 14 to 40, for example from 14 to 30, such as from 14 to 20, for example from 14 to 16, such as from 16 to 100, such as from 16 to 80, for example from 16 to 60, such as from 16 to 40, for example from 16 to 30, such as from 16 to 20, such as from 18 to 100, such as from 18 to 80, for example from 18 to 60, such as from 18 to 40, for example from 18 to 30, such as from 18 to 20, for example from 20 to 100, such as from 20 to 80, for example from 20 to 60, such as from 20 to 40, for example from 20 to 30, such as from 20 to 25, for example from 22 to 100, such as from 22 to 80, for example from 22 to 60, such as from 22 to 40, for example from 22 to 30, such as from 22 to 25, for example from 25 to 100, such as from 25 to 80, for example from 25 to 60, such as from 25 to 40, for example from 25 to 30, such as from 30 to 100, for example from 30 to 80, such as from 30 to 60, for example from 30 to 40, such as from 30 to 35, for example from 35 to 100, such as from 35 to 80, for example from 35 to 60, such as from 35 to 40, for example from 40 to 100, such as from 40 to 80, for example from 40 to 60, such as from 40 to 50, for example from 40 to 45, such as from 45 to 100, for example from 45 to 80, such as from 45 to 60, for example from 45 to 50, such as from 50 to 100, for example from 50 to 80, such as from 50 to 60, for example from 50 to 55, such as from 60 to 100, for example from 60 to 80, such as from 60 to 70, for example from 70 to 100, such as from 70 to 90, for example from 70 to 80, such as from 80 to 100, for example from 80 to 90, such as from 90 to 100.

[0388] In some embodiments of the invention it is preferred that the template is attached to a solid or semi-solid support.

[0389] The template in one embodiment preferably comprises or essentially consists of nucleotides selected from the group consisting of deoxyribonucleic acids (DNA), ribonucleic acids (RNA), peptide nucleic acids (PNA), locked nucleic acids (LNA), and morpholinos sequences, including any analog or derivative thereof.

[0390] In another embodiment, the template of coding elements preferably comprises or essentially consists of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholinos sequence, including any analog or derivative thereof, and the complementing element preferably comprises or essentially consists of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholinos sequence, including any analog or derivative thereof.

[0391] It is preferred in various embodiments of the invention that the template can be characterised by any one or more of the following features: i) That the template is amplifiable, ii) that the template comprises a single strand of coding elements, preferably a single strand of coding elements capable of forming a double helix by hybridization to a complementing template comprising a single strand of complementing elements, and iii) that the template comprises a priming site.

Coding elements

[0392] Each coding element is preferably linked to a neighbouring coding element by a covalent chemical bond. Each

coding element can also be linked to each neighbouring coding element by a covalent chemical bond. The covalent chemical bond is preferably selected from the group of covalent bonds consisting of phosphodiester bonds, phosphorothioate bonds, and peptide bonds. More preferably, the covalent chemical bond is selected from the group of covalent bonds consisting of phosphodiester bonds and phosphorothioate bonds.

[0393] In preferred embodiments, at least one coding element is attached to a solid or semi-solid support.

[0394] The coding elements are selected in one embodiment of the invention from the group consisting of nucleotides, including any analog or derivative thereof, amino acids, antibodies, and antigens, and preferably from the group consisting of nucleotides, nucleotide derivatives, and nucleotide analogs, including any combination thereof. In another embodiment, the coding elements are selected from the group consisting of nucleotides, including nucleotides such as deoxyribonucleic acids comprising a base selected from adenine (A), thymine (T), guanine (G), and cytosine (C), and ribonucleic acids comprising a base selected from adenine (A), uracil (U), guanine (G), and cytosine (C). Also in this case can each nucleotide be linked to a neighbouring nucleotide by means of a covalent bond, or linked to each neighbouring nucleotide by means of a covalent bond. The covalent bond is preferably a phosphodiester bond or a phosphorothioate bond.

[0395] In other embodiments, the coding elements are natural and non-natural nucleotides selected from the group consisting of deoxyribonucleic acids and ribonucleic acids.

Coding Elements and Corresponding Complementing Elements

[0396] When the coding elements are preferably selected from the group consisting of nucleotides, nucleotide derivatives and nucleotide analogs in which one or more of the base moiety and/or the phosphate moiety and/or the ribose or deoxyribose moiety have been substituted by an alternative molecular entity, corresponding complementing elements are capable of interacting with said coding elements and preferably comprise or essentially consist of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholinos sequence, including any analog or derivative thereof. Each nucleotide is linked to a neighbouring nucleotide by a covalent chemical bond, or linked to each neighbouring nucleotide by a covalent chemical bond. The covalent chemical bond is preferably selected from the group of covalent bonds consisting of phosphodiester bonds and peptide bonds.

Coding Element Subunits

[0397] Coding elements in one embodiment preferably comprise or essentially consist of from 1 to 100 subunits, such as from 1 to 80 subunits, for example from 1 to 60 subunits, such as from 1 to 40 subunits, for example from 1 to 20 subunits, such as from 1 to 18 subunits, for example from 1 to 16 subunits, such as from 1 to 14 subunits, for example from 1 to 12 subunits, such as from 1 to 10 subunits, for example from 1 to 9 subunits, such as from 1 to 8 subunits, for example from 1 to 7 subunits, such as from 1 to 6 subunits, for example from 1 to 5 subunits, such as from 1 to 4 subunits, for example from 1 to 3 subunits, such as from 1 to 2 subunits, for example 1 subunit, such as from 2 to 100 subunits, such as from 2 to 80 subunits, for example from 2 to 60 subunits, such as from 2 to 40 subunits, for example from 2 to 20 subunits, such as from 2 to 18 subunits, for example from 2 to 16 subunits, such as from 2 to 14 subunits, for example from 2 to 12 subunits, such as from 2 to 10 subunits, for example from 2 to 9 subunits, such as from 2 to 8 subunits, for example from 2 to 7 subunits, such as from 2 to 6 subunits, for example from 2 to 5 subunits, such as from 2 to 4 subunits, for example from 2 to 3 subunits, such as 2 subunits, such as from 3 to 100 subunits, such as from 3 to 80 subunits, for example from 3 to 60 subunits, such as from 3 to 40 subunits, for example from 3 to 20 subunits, such as from 3 to 18 subunits, for example from 3 to 16 subunits, such as from 3 to 14 subunits, for example from 3 to 12 subunits, such as from 3 to 10 subunits, for example from 3 to 9 subunits, such as from 3 to 8 subunits, for example from 3 to 7 subunits, such as from 3 to 6 subunits, for example from 3 to 5 subunits, such as from 3 to 4 subunits, for example 3 subunits, for example from 4 to 100 subunits, such as from 4 to 80 subunits, for example from 4 to 60 subunits, such as from 4 to 40 subunits, for example from 4 to 20 subunits, such as from 4 to 18 subunits, for example from 4 to 16 subunits, such as from 4 to 14 subunits, for example from 4 to 12 subunits, such as from 4 to 10 subunits, for example from 4 to 9 subunits, such as from 4 to 8 subunits, for example from 4 to 7 subunits, such as from 4 to 6 subunits, for example from 4 to 5 subunits, for example 4 subunits, such as from 5 to 100 subunits, such as from 5 to 80 subunits, for example from 5 to 60 subunits, such as from 5 to 40 subunits, for example from 5 to 20 subunits, such as from 5 to 18 subunits, for example from 5 to 16 subunits, such as from 5 to 14 subunits, for example from 5 to 12 subunits, such as from 5 to 10 subunits, for example from 5 to 9 subunits, such as from 5 to 8 subunits, for example from 5 to 7 subunits, such as from 5 to 6 subunits, such as 5 subunits, for example from 6 to 100 subunits, such as from 6 to 80 subunits, for example from 6 to 60 subunits, such as from 6 to 40 subunits, for example from 6 to 20 subunits, such as from 6 to 18 subunits, for example from 6 to 16 subunits, such as from 6 to 14 subunits, for example from 6 to 12 subunits, such as from 6 to 10 subunits, for example from 6 to 9 subunits, such as from 6 to 8 subunits, for example from 6 to 7 subunits, such as 6 subunits, such as from 7 to 100 subunits, such as from 7 to 80 subunits, for example from 7 to 60 subunits, such as from 7 to 40 subunits, for example from 7 to 20 subunits, such as from 7 to 18 subunits, for example from 7 to 16 subunits,

such as from 7 to 14 subunits, for example from 7 to 12 subunits, such as from 7 to 10 subunits, for example from 7 to 9 subunits, such as from 7 to 8 subunits, such as 7 subunits, for example from 8 to 100 subunits, such as from 8 to 80 subunits, for example from 8 to 60 subunits, such as from 8 to 40 subunits, for example from 8 to 20 subunits, such as from 8 to 18 subunits, for example from 8 to 16 subunits, such as from 8 to 14 subunits, for example from 8 to 12 subunits, such as from 8 to 10 subunits, for example from 8 to 9 subunits, for example 8 subunits, such as from 9 to 100 subunits, such as from 9 to 80 subunits, for example from 9 to 60 subunits, such as from 9 to 40 subunits, for example from 9 to 20 subunits, such as from 9 to 18 subunits, for example from 9 to 16 subunits, such as from 9 to 14 subunits, for example from 9 to 12 subunits, such as from 9 to 10 subunits, such as 9 subunits, for example from 10 to 100 subunits, such as from 10 to 80 subunits, for example from 10 to 60 subunits, such as from 10 to 40 subunits, for example from 10 to 20 subunits, such as from 10 to 18 subunits, for example from 10 to 16 subunits, such as from 10 to 14 subunits, for example from 10 to 12 subunits, such as 10 subunits, such as from 11 to 100 subunits, such as from 11 to 80 subunits, for example from 11 to 60 subunits, such as from 11 to 40 subunits, for example from 11 to 20 subunits, such as from 11 to 18 subunits, for example from 11 to 16 subunits, such as from 11 to 14 subunits, for example from 11 to 12 subunits, such as from 12 to 100 subunits, such as from 12 to 80 subunits, for example from 12 to 60 subunits, such as from 12 to 40 subunits, for example from 12 to 20 subunits, such as from 12 to 18 subunits, for example from 12 to 16 subunits, such as from 12 to 14 subunits, for example from 13 to 100 subunits, such as from 13 to 80 subunits, for example from 13 to 60 subunits, such as from 13 to 40 subunits, for example from 13 to 20 subunits, such as from 13 to 18 subunits, for example from 13 to 16 subunits, such as from 13 to 14 subunits, for example from 14 to 100 subunits, such as from 14 to 80 subunits, for example from 14 to 60 subunits, such as from 14 to 40 subunits, for example from 14 to 20 subunits, such as from 14 to 18 subunits, for example from 14 to 16 subunits, such as from 15 to 100 subunits, such as from 15 to 80 subunits, for example from 15 to 60 subunits, such as from 15 to 40 subunits, for example from 15 to 20 subunits, such as from 15 to 18 subunits, for example from 15 to 16 subunits, such as from 16 to 100 subunits, such as from 16 to 80 subunits, for example from 16 to 60 subunits, such as from 16 to 40 subunits, for example from 16 to 20 subunits, such as from 16 to 18 subunits, for example from 17 to 100 subunits, such as from 17 to 80 subunits, for example from 17 to 60 subunits, such as from 17 to 40 subunits, for example from 17 to 20 subunits, such as from 17 to 18 subunits, for example from 18 to 100 subunits, such as from 18 to 80 subunits, for example from 18 to 60 subunits, such as from 18 to 40 subunits, for example from 18 to 20 subunits, such as from 19 to 100 subunits, such as from 19 to 80 subunits, for example from 19 to 60 subunits, such as from 19 to 40 subunits, for example from 19 to 30 subunits, such as from 19 to 25 subunits, for example from 20 to 100 subunits, such as from 20 to 80 subunits, for example from 20 to 60 subunits, such as from 20 to 40 subunits, for example from 20 to 30 subunits, such as from 20 to 25 subunits.

[0398] In preferred embodiments, each coding element subunit comprises or essentially consists of a nucleotide, or a nucleotide analog. The nucleotide can be a deoxyribonucleic acid comprising a base selected from adenine (A), thymine (T), guanine (G), and cytosine (C), or it can be a ribonucleic acid comprising a base selected from adenine (A), uracil (U), guanine (G), and cytosine (C). Each nucleotide is linked to a neighbouring nucleotide, or nucleotide analog, by means of a covalent bond, or linked to each neighbouring nucleotide, or nucleotide analog, by means of a covalent bond, including covalent bonds selected from the group consisting of phosphodiester bonds, phosphorothioate bonds, and peptide bonds.

[0399] In one embodiment it is preferred that at least some of said nucleotides are selected from the group consisting of nucleotide derivatives, including deoxyribonucleic acid derivatives and ribonucleic acid derivatives.

Coding Element Subunits and Corresponding Complementing Element Subunits

[0400] The coding element subunits are preferably selected from the group consisting of nucleotides, nucleotide derivatives and nucleotide analogs in which one or more of a base moiety and/or a phosphate moiety and/or a ribose moiety and/or a deoxyribose moiety have been substituted by an alternative molecular entity, and the corresponding complementing element subunits capable of interacting with said coding element subunits comprise or essentially consist of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholinos sequence, including any analog or derivative thereof.

[0401] Each nucleotide derivative can be linked to a neighbouring nucleotide, or nucleotide analog, by a covalent chemical bond, or each nucleotide derivative can be linked to each neighbouring nucleotide, or nucleotide analog, by a covalent chemical bond. The covalent chemical bond is preferably selected from the group of covalent bonds consisting of phosphodiester bonds, phosphorothioate bonds, and peptide bonds.

Complementing Elements

[0402] The complementing template in one embodiment preferably comprises n complementing elements in a linear sequence or a branched sequence. n preferably has a value of from 2 to 200, for example from 2 to 100, such as from 2 to 80, for example from 2 to 60, such as from 2 to 40, for example from 2 to 30, such as from 2 to 20, for example

from 2 to 15, such as from 2 to 10, such as from 2 to 8, for example from 2 to 6, such as from 2 to 4, such as 2, such as from 3 to 100, for example from 3 to 80, such as from 3 to 60, such as from 3 to 40, for example from 3 to 30, such as from 3 to 20, such as from 3 to 15, for example from 3 to 15, such as from 3 to 10, such as from 3 to 8, for example from 3 to 6, such as from 3 to 4, for example 3, such as from 4 to 100, for example from 4 to 80, such as from 4 to 60, such as from 4 to 40, for example from 4 to 30, such as from 4 to 20, such as from 4 to 15, for example from 4 to 10, such as from 4 to 8, such as from 4 to 6, such as 4, for example from 5 to 100, such as from 5 to 80, for example from 5 to 60, such as from 5 to 40, for example from 5 to 30, such as from 5 to 20, for example from 5 to 15, such as from 5 to 10, such as from 5 to 8, for example from 5 to 6, for example 5, such as from 6 to 100, for example from 6 to 80, such as from 6 to 60, such as from 6 to 40, for example from 6 to 30, such as from 6 to 20, such as from 6 to 15, for example from 6 to 10, such as from 6 to 8, such as 6, for example from 7 to 100, such as from 7 to 80, for example from 7 to 60, such as from 7 to 40, for example from 7 to 30, such as from 7 to 20, for example from 7 to 15, such as from 7 to 10, such as from 7 to 8, such as 7, for example from 8 to 100, such as from 8 to 80, for example from 8 to 60, such as from 8 to 40, for example from 8 to 30, such as from 8 to 20, for example from 8 to 15, such as from 8 to 10, for example 8, such as 9, for example from 10 to 100, such as from 10 to 80, for example from 10 to 60, such as from 10 to 40, for example from 10 to 30, such as from 10 to 20, for example from 10 to 15, such as from 10 to 12, such as 10, for example from 12 to 100, such as from 12 to 80, for example from 12 to 60, such as from 12 to 40, for example from 12 to 30, such as from 12 to 20, for example from 12 to 15, such as from 14 to 100, such as from 14 to 80, for example from 14 to 60, such as from 14 to 40, for example from 14 to 30, such as from 14 to 20, for example from 14 to 16, such as from 16 to 100, such as from 16 to 80, for example from 16 to 60, such as from 16 to 40, for example from 16 to 30, such as from 16 to 20, such as from 18 to 100, such as from 18 to 80, for example from 18 to 60, such as from 18 to 40, for example from 18 to 30, such as from 18 to 20, for example from 20 to 100, such as from 20 to 80, for example from 20 to 60, such as from 20 to 40, for example from 20 to 30, such as from 20 to 25, for example from 22 to 100, such as from 22 to 80, for example from 22 to 60, such as from 22 to 40, for example from 22 to 30, such as from 22 to 25, for example from 25 to 100, such as from 25 to 80, for example from 25 to 60, such as from 25 to 40, for example from 25 to 30, such as from 30 to 100, for example from 30 to 80, such as from 30 to 60, for example from 30 to 40, such as from 30 to 35, for example from 35 to 100, such as from 35 to 80, for example from 35 to 60, such as from 35 to 40, for example from 40 to 100, such as from 40 to 80, for example from 40 to 60, such as from 40 to 50, for example from 40 to 45, such as from 45 to 100, for example from 45 to 80, such as from 45 to 60, for example from 45 to 50, such as from 50 to 100, for example from 50 to 80, such as from 50 to 60, for example from 50 to 55, such as from 60 to 100, for example from 60 to 80, such as from 60 to 70, for example from 70 to 100, such as from 70 to 90, for example from 70 to 80, such as from 80 to 100, for example from 80 to 90, such as from 90 to 100.

[0403] In some embodiments, the complementing template is attached to a solid or semi-solid support.

[0404] The complementing template in one embodiment comprises or essentially consists of nucleotides selected from the group consisting of deoxyribonucleic acids (DNA), ribonucleic acids (RNA), peptide nucleic acids (PNA), locked nucleic acids (LNA), and morpholinos sequences, including any analog or derivative thereof.

[0405] In other embodiments, there is provided a complementing template comprising or essentially consisting of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholinos sequence, including any analog or derivative thereof, wherein the corresponding coding elements of the template comprise or essentially consist of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholinos sequence, including any analog or derivative thereof.

[0406] The complementing template is preferably amplifiable and/or comprises a single strand of complementing elements and/or comprises a single strand of complementing elements capable of forming a double helix by hybridization to a template comprising a single strand of coding elements, and/or comprises a priming site.

[0407] Each complementing element is preferably linked to a neighbouring complementing element by a covalent chemical bond, or linked to each complementing element is linked to each neighbouring complementing element by a covalent chemical bond. The covalent chemical bond is in one embodiment selected from the group of covalent bonds consisting of phosphodiester bonds, phosphorothioate bonds, and peptide bonds. In other embodiments, the group of covalent bonds consist of phosphodiester bonds and phosphorothioate bonds.

[0408] The at least one complementing element can be attached to a solid or semi-solid support.

[0409] The complementing elements can be selected from the group consisting of nucleotides, including any analog or derivative thereof, amino acids, antibodies, and antigens, and preferably from the group consisting of nucleotides, nucleotide derivatives, and nucleotide analogs, including any combination thereof. In one embodiment, it is preferred that the complementing elements are selected from the group consisting of nucleotides, including deoxyribonucleic acids comprising a base selected from adenine (A), thymine (T), guanine (G), and cytosine (C), and ribonucleic acids comprising a base selected from adenine (A), uracil (U), guanine (G), and cytosine (C).

[0410] Each nucleotide can be linked to a neighbouring nucleotide, or nucleotide analog, by means of a covalent bond, including, or each nucleotide can be linked to each neighbouring nucleotide, or nucleotide analog, by means of a covalent bond. The covalent bond can be a phosphodiester bond or a phosphorothioate bond.

[0411] In another embodiment, the complementing elements are natural or non-natural nucleotides selected from the group consisting of deoxyribonucleic acids and ribonucleic acids.

Complementing Elements and Corresponding Coding Elements

[0412] When the complementing elements are selected from the group consisting of nucleotides, nucleotide derivatives and nucleotide analogs in which one or more of a base moiety and/or a phosphate moiety and/or a ribose and/or a deoxyribose moiety has been substituted by an alternative molecular entity, the coding elements capable of interacting with said complementing elements comprise or essentially consist of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholinos sequence, including any analog or derivative thereof.

[0413] Each nucleotide can be linked to a neighbouring nucleotide, or nucleotide analog, by a covalent chemical bond, or linked to each neighbouring nucleotide, or nucleotide analog, by a covalent chemical bond. The covalent chemical bond is preferably selected from the group of covalent bonds consisting of phosphodiester bonds, phosphorothioate bonds, and peptide bonds.

[0414] The complementing elements are in one embodiment selected from nucleotides, and the complementing elements can in one preferred embodiment be linked enzymatically by using an enzyme selected from the group consisting of template-dependent DNA- and RNA-polymerases, including reverse transcriptases, DNA-ligases and RNA-ligases, ribozymes and deoxyribozymes, including HIV-1 Reverse Transcriptase, AMV Reverse Transcriptase, T7 RNA polymerase, T7 RNA polymerase mutant Y639F, Sequenase, Taq DNA polymerase, Klenow Fragment (Large fragment of DNA polymerase I), DNA-ligase, T7 DNA polymerase, T4 DNA polymerase, T4 DNA Ligase, E. coli RNA polymerase, rTh DNA polymerase, Vent DNA polymerase, Pfu DNA polymerase, Tte DNA polymerase, and ribozymes with ligase or replicase activities.

[0415] More preferably, the enzyme is selected from the group consisting of HIV-1 Reverse Transcriptase, AMV Reverse Transcriptase, T7 RNA polymerase, T7 RNA polymerase mutant Y639F, Sequenase, Taq DNA polymerase, Klenow Fragment (Large fragment of DNA polymerase I), DNA-ligase, T7 DNA polymerase, T4 DNA polymerase, and T4 DNA Ligase. The nucleotides preferably form a template or complementing template upon incorporation.

[0416] In another embodiment, the complementing elements can be selected from nucleotides, and linked by using a chemical agent, pH change, light, a catalyst, radiation, such as electromagnetic radiation, or by spontaneous coupling when being brought into reactive contact with each other.

Complementing Element Subunits

[0417] The complementing element preferably comprises or essentially consists of from 1 to 100 subunits, such as from 1 to 80 subunits, for example from 1 to 60 subunits, such as from 1 to 40 subunits, for example from 1 to 20 subunits, such as from 1 to 18 subunits, for example from 1 to 16 subunits, such as from 1 to 14 subunits, for example from 1 to 12 subunits, such as from 1 to 10 subunits, for example from 1 to 9 subunits, such as from 1 to 8 subunits, for example from 1 to 7 subunits, such as from 1 to 6 subunits, for example from 1 to 5 subunits, such as from 1 to 4 subunits, for example from 1 to 3 subunits, such as from 1 to 2 subunits, for example 1 subunit, such as from 2 to 100 subunits, such as from 2 to 80 subunits, for example from 2 to 60 subunits, such as from 2 to 40 subunits, for example from 2 to 20 subunits, such as from 2 to 18 subunits, for example from 2 to 16 subunits, such as from 2 to 14 subunits, for example from 2 to 12 subunits, such as from 2 to 10 subunits, for example from 2 to 9 subunits, such as from 2 to 8 subunits, for example from 2 to 7 subunits, such as from 2 to 6 subunits, for example from 2 to 5 subunits, such as from 2 to 4 subunits, for example from 2 to 3 subunits, such as 2 subunits, such as from 3 to 100 subunits, such as from 3 to 80 subunits, for example from 3 to 60 subunits, such as from 3 to 40 subunits, for example from 3 to 20 subunits, such as from 3 to 18 subunits, for example from 3 to 16 subunits, such as from 3 to 14 subunits, for example from 3 to 12 subunits, such as from 3 to 10 subunits, for example from 3 to 9 subunits, such as from 3 to 8 subunits, for example from 3 to 7 subunits, such as from 3 to 6 subunits, for example from 3 to 5 subunits, such as from 3 to 4 subunits, for example 3 subunits, for example from 4 to 100 subunits, such as from 4 to 80 subunits, for example from 4 to 60 subunits, such as from 4 to 40 subunits, for example from 4 to 20 subunits, such as from 4 to 18 subunits, for example from 4 to 16 subunits, such as from 4 to 14 subunits, for example from 4 to 12 subunits, such as from 4 to 10 subunits, for example from 4 to 9 subunits, such as from 4 to 8 subunits, for example from 4 to 7 subunits, such as from 4 to 6 subunits, for example from 4 to 5 subunits, for example 4 subunits, such as from 5 to 100 subunits, such as from 5 to 80 subunits, for example from 5 to 60 subunits, such as from 5 to 40 subunits, for example from 5 to 20 subunits, such as from 5 to 18 subunits, for example from 5 to 16 subunits, such as from 5 to 14 subunits, for example from 5 to 12 subunits, such as from 5 to 10 subunits, for example from 5 to 9 subunits, such as from 5 to 8 subunits, for example from 5 to 7 subunits, such as from 5 to 6 subunits, such as 5 subunits, for example from 6 to 100 subunits, such as from 6 to 80 subunits, for example from 6 to 60 subunits, such as from 6 to 40 subunits, for example from 6 to 20 subunits, such as from 6 to 18 subunits, for example from 6 to 16 subunits, such as from 6 to 14 subunits, for example from 6 to 12 subunits, such as from 6 to

10 subunits, for example from 6 to 9 subunits, such as from 6 to 8 subunits, for example from 6 to 7 subunits, such as 6 subunits, such as from 7 to 100 subunits, such as from 7 to 80 subunits, for example from 7 to 60 subunits, such as from 7 to 40 subunits, for example from 7 to 20 subunits, such as from 7 to 18 subunits, for example from 7 to 16 subunits, such as from 7 to 14 subunits, for example from 7 to 12 subunits, such as from 7 to 10 subunits, for example from 7 to 9 subunits, such as from 7 to 8 subunits, such as 7 subunits, for example from 8 to 100 subunits, such as from 8 to 80 subunits, for example from 8 to 60 subunits, such as from 8 to 40 subunits, for example from 8 to 20 subunits, such as from 8 to 18 subunits, for example from 8 to 16 subunits, such as from 8 to 14 subunits, for example from 8 to 12 subunits, such as from 8 to 10 subunits, for example from 8 to 9 subunits, for example 8 subunits, such as from 9 to 100 subunits, such as from 9 to 80 subunits, for example from 9 to 60 subunits, such as from 9 to 40 subunits, for example from 9 to 20 subunits, such as from 9 to 18 subunits, for example from 9 to 16 subunits, such as from 9 to 14 subunits, for example from 9 to 12 subunits, such as from 9 to 10 subunits, such as 9 subunits, for example from 10 to 100 subunits, such as from 10 to 80 subunits, for example from 10 to 60 subunits, such as from 10 to 40 subunits, for example from 10 to 20 subunits, such as from 10 to 18 subunits, for example from 10 to 16 subunits, such as from 10 to 14 subunits, for example from 10 to 12 subunits, such as 10 subunits, such as from 11 to 100 subunits, such as from 11 to 80 subunits, for example from 11 to 60 subunits, such as from 11 to 40 subunits, for example from 11 to 20 subunits, such as from 11 to 18 subunits, for example from 11 to 16 subunits, such as from 11 to 14 subunits, for example from 11 to 12 subunits, such as from 12 to 100 subunits, such as from 12 to 80 subunits, for example from 12 to 60 subunits, such as from 12 to 40 subunits, for example from 12 to 20 subunits, such as from 12 to 18 subunits, for example from 12 to 16 subunits, such as from 12 to 14 subunits, for example from 13 to 100 subunits, such as from 13 to 80 subunits, for example from 13 to 60 subunits, such as from 13 to 40 subunits, for example from 13 to 20 subunits, such as from 13 to 18 subunits, for example from 13 to 16 subunits, such as from 13 to 14 subunits, for example from 14 to 100 subunits, such as from 14 to 80 subunits, for example from 14 to 60 subunits, such as from 14 to 40 subunits, for example from 14 to 20 subunits, such as from 14 to 18 subunits, for example from 14 to 16 subunits, such as from 15 to 100 subunits, such as from 15 to 80 subunits, for example from 15 to 60 subunits, such as from 15 to 40 subunits, for example from 15 to 20 subunits, such as from 15 to 18 subunits, for example from 15 to 16 subunits, such as from 16 to 100 subunits, such as from 16 to 80 subunits, for example from 16 to 60 subunits, such as from 16 to 40 subunits, for example from 16 to 20 subunits, such as from 16 to 18 subunits, for example from 17 to 100 subunits, such as from 17 to 80 subunits, for example from 17 to 60 subunits, such as from 17 to 40 subunits, for example from 17 to 20 subunits, such as from 17 to 18 subunits, for example from 18 to 100 subunits, such as from 18 to 80 subunits, for example from 18 to 60 subunits, such as from 18 to 40 subunits, for example from 18 to 20 subunits, such as from 19 to 100 subunits, such as from 19 to 80 subunits, for example from 19 to 60 subunits, such as from 19 to 40 subunits, for example from 19 to 30 subunits, such as from 19 to 25 subunits, for example from 20 to 100 subunits, such as from 20 to 80 subunits, for example from 20 to 60 subunits, such as from 20 to 40 subunits, for example from 20 to 30 subunits, such as from 20 to 25 subunits.

[0418] In preferred embodiments, each subunit comprises or essentially consists of a nucleotide, or a nucleotide analog. The nucleotide can be a deoxyribonucleic acid comprising a base selected from adenine (A), thymine (T), guanine (G), and cytosine (C), or a ribonucleic acid comprising a base selected from adenine (A), uracil (U), guanine (G), and cytosine (C).

[0419] Each of said nucleotides can be linked to a neighbouring nucleotide, or nucleotide analog, by means of a covalent bond, or linked to each neighbouring nucleotide, or nucleotide analog, by means of a covalent bond. The covalent bond is preferably selected from the group consisting of phosphodiester bonds, phosphorothioate bonds, and peptide bonds.

[0420] It is preferred in one embodiment that at least some of said nucleotides are selected from the group consisting of nucleotide derivatives, including nucleotide derivatives selected from the group consisting of deoxyribonucleic acid derivatives and ribonucleic acid derivatives.

Complementing Element Subunits and Corresponding Coding Element Subunits

[0421] When the complementing element subunits are selected from the group consisting of nucleotides, nucleotide derivatives, and nucleotide analogs in which one or more of a base moiety and/or a phosphate moiety and/or a ribose moiety and/or a deoxyribose moiety has been substituted by an alternative molecular entity, the coding element subunits capable of interacting with said complementing element subunits preferably comprise or essentially consist of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholinos sequence, including any analog or derivative thereof.

[0422] It is preferred that each nucleotide derivative is linked to a neighbouring nucleotide, or nucleotide analog, by a covalent chemical bond, or linked to each neighbouring nucleotide, or nucleotide analog, by a covalent chemical bond. The covalent chemical bond can be selected from the group of covalent bonds consisting of phosphodiester bonds, phosphorothioate bonds, and peptide bonds.

Building Blocks, Cleavable Linkers and Selectively Cleavable Linkers

[0423] In one aspect there is provided a building block comprising

i) a complementing element capable of specifically recognising a coding element having a recognition group, said complementing element being selected from nucleotides, amino acids, antibodies, antigens, proteins, peptides, and molecules with nucleotide recognizing ability,

ii) at least one functional entity selected from a precursor of α -peptides, β -peptides, γ -peptides, ω -peptides, mono-, di- and tri-substituted α -peptides, β -peptides, γ -peptides, ω -peptides, peptides wherein the amino acid residues are in the L-form or in the D-form, vinylogous polypeptides, glycopoly-peptides, polyamides, vinylogous sulfonamide peptide, polysulfonamide, conjugated peptides comprising e.g. prosthetic groups, polyesters, polysaccharides, polycarbamates, polycarbonates, polyureas, polypeptidylphosphonates, polyurethanes, azatides, oligo N-substituted glycines, polyethers, ethoxyformacetal oligomers, poly-thioethers, polyethylene glycols (PEG), polyethylenes, polydisulfides, polyarylene sulfides, polynucleotides, PNAs, LNAs, morpholinos, oligo pyrrolinone, polyoximes, polyimines, polyethyleneimines, polyimides, polyacetals, polyacetates, polystyrenes, polyvinyl, lipids, phospholipids, glycolipids, polycyclic compounds comprising e.g. aliphatic or aromatic cycles, including polyheterocyclic compounds, proteoglycans, and polysiloxanes, and

iii) a linker or selectively cleavable linker separating the functional entity from the complementing element.

[0424] The complementing element of the building block is preferably selected from a nucleotide sequence, such as a sequence of from 1 to 8 nucleotides, such as from 1 to 6 nucleotides, for example from 1 to 4 nucleotides, such as from 1 to 3 nucleotides, such as 2 nucleotides or for example 3 nucleotides.

[0425] The functional entity can be selected from a precursor of an amino acid selected from alfa amino acids, beta amino acids, gamma amino acids, di-substituted amino acids, poly-substituted amino acids, vinylogous amino acids, N-substituted glycin derivatives and other modified amino acids.

[0426] The is also provided a composition of building blocks as defined herein, wherein at least two building blocks of the composition are different.

[0427] At least a subset of the plurality of building blocks preferably comprises one complementing element and one functional entity and one linker.

[0428] In one embodiment, each building block comprises at least one reactive group type I and/or at least one reactive group type II, including one reactive group type I, two reactive groups type I, one reactive group type II, and two reactive groups type II.

[0429] At least one of said reactive groups type II of the functional entity is preferably selected from the group consisting of N-carboxyanhydride (NCA), N-thiocarboxyanhydride (NTA), amine, carboxylic acid, ketone, aldehyde, hydroxyl, thiol, ester, thioester, any conjugated system of double bonds, hydrazine, N-hydroxysuccinimide ester, and epoxide.

[0430] In some embodiments, the ractive group type II is an electrophile, a nucleophile, or a radical.

[0431] At least a subset of said plurality of building blocks comprises a selectively cleavable linker separating the functional entity from the complementing element, wherein said selectively cleavable linker is not cleaved under conditions resulting in cleavage of cleavable linkers separating the functional entity from the complementing element of building blocks not belonging to the subset of building blocks comprising a selectively cleavable linker. The cleavable linkers of the building blocks are cleaved without cleaving the at least one selectively cleavable linker linking the templated molecule to the complementing template, or to a complementing element, or linking said templated molecule to a templating element, or to the template that templated the synthesis of the templated molecule.

[0432] Linkers and selectively cleavable linkers can be cleaved by e.g. acid, base, a chemical agent, light, electromagnetic radiation, an enzyme, or a catalyst, with the proviso that the cleavage of the cleavable linker does result in the cleavage of the selectively cleavable linker unless this is desirable.

[0433] In one embodiment, the length of the linker or selectively cleavable linker is in the range of from about 0.8 Å to about 70 Å, such as in the range of from 0.8 Å to about 60 Å, for example in the range of from 0.8 Å to about 50 Å, such as in the range of from 0.8 Å to about 40 Å, for example in the range of from 0.8 Å to about 30 Å, such as in the range of from 0.8 Å to about 25 Å, for example in the range of from 0.8 Å to about 20 Å, such as in the range of from 0.8 Å to about 18 Å, for example in the range of from 0.8 Å to about 16 Å, such as in the range of from 0.8 Å to about 14 Å, for example in the range of from 0.8 Å to about 12 Å, such as in the range of from 0.8 Å to about 10 Å, for example in the range of from 0.8 Å to about 8 Å, such as in the range of from 0.8 Å to about 7 Å, for example in the range of from 0.8 Å to about 6 Å, such as in the range of from 0.8 Å to about 5 Å, for example in the range of from 0.8 Å to about 4 Å, such as in the range of from 0.8 Å to about 3.5 Å, for example in the range of from 0.8 Å to about 3.0 Å, such as in the range of from 0.8 Å to about 2.5 Å, for example in the range of from 0.8 Å to about 2.0 Å, such as in the range of from

0.8 Å to about 1.5 Å, for example in the range of from 0.8 Å to about 1.0 Å.

[0434] In another embodiment, the length of the linker or selectively cleavable linker is in the range of from about 1 Å to about 60 Å, such as in the range of from 1 Å to about 40 Å, for example in the range of from 1 Å to about 30 Å, such as in the range of from 1 Å to about 25 Å, for example in the range of from 1 Å to about 20 Å, such as in the range of from 1 Å to about 18 Å, for example in the range of from 1 Å to about 16 Å, such as in the range of from 1 Å to about 14 Å, for example in the range of from 1 Å to about 12 Å, such as in the range of from 1 Å to about 10 Å, for example in the range of from 1 Å to about 8 Å, such as in the range of from 1 Å to about 7 Å, for example in the range of from 1 Å to about 6 Å, such as in the range of from 1 Å to about 5 Å, for example in the range of from 1 Å to about 4 Å, such as in the range of from 1.0 Å to about 3.5 Å, for example in the range of from 1.0 Å to about 3.0 Å, such as in the range of from 1.0 Å to about 2.5 Å, for example in the range of from 1.0 Å to about 2.0 Å, such as in the range of from 1.0 Å to about 1.5 Å, for example in the range of from 1.0 Å to about 1.2 Å.

[0435] In yet another embodiment, the length of the linker or selectively cleavable linker is in the range of from about 2 Å to about 40 Å, such as in the range of from 2 Å to about 30 Å, such as in the range of from 2 Å to about 25 Å, for example in the range of from 2 Å to about 20 Å, such as in the range of from 2 Å to about 18 Å, for example in the range of from 2 Å to about 16 Å, such as in the range of from 2 Å to about 14 Å, for example in the range of from 2 Å to about 12 Å, such as in the range of from 2 Å to about 10 Å, for example in the range of from 2 Å to about 8 Å, such as in the range of from 2 Å to about 7 Å, for example in the range of from 2 Å to about 6 Å, such as in the range of from 2 Å to about 5 Å, for example in the range of from 2 Å to about 4 Å, such as in the range of from 2.0 Å to about 3.5 Å, for example in the range of from 2.0 Å to about 3.0 Å, such as in the range of from 2.0 Å to about 2.5 Å, for example in the range of from 2.0 Å to about 2.2 Å.

[0436] In a further embodiment, the length of the linker or selectively cleavable linker is in the range of from about 4 Å to about 40 Å, such as in the range of from 4 Å to about 30 Å, such as in the range of from 4 Å to about 25 Å, for example in the range of from 4 Å to about 20 Å, such as in the range of from 4 Å to about 18 Å, for example in the range of from 4 Å to about 16 Å, such as in the range of from 4 Å to about 14 Å, for example in the range of from 4 Å to about 12 Å, such as in the range of from 4 Å to about 10 Å, for example in the range of from 4 Å to about 8 Å, such as in the range of from 4 Å to about 7 Å, for example in the range of from 4 Å to about 6 Å, such as in the range of from 4 Å to about 5 Å.

[0437] In a still further embodiment, the length of the linker or selectively cleavable linker is in the range of from about 6 Å to about 40 Å, such as in the range of from 6 Å to about 30 Å, such as in the range of from 6 Å to about 25 Å, for example in the range of from 6 Å to about 20 Å, such as in the range of from 6 Å to about 18 Å, for example in the range of from 6 Å to about 16 Å, such as in the range of from 6 Å to about 14 Å, for example in the range of from 6 Å to about 12 Å, such as in the range of from 6 Å to about 10 Å, for example in the range of from 6 Å to about 8 Å, such as in the range of from 6 Å to about 7 Å.

[0438] In yet another embodiment, the length of the linker or selectively cleavable linker is in the range of from about 8 Å to about 40 Å, such as in the range of from 8 Å to about 30 Å, such as in the range of from 8 Å to about 25 Å, for example in the range of from 8 Å to about 20 Å, such as in the range of from 8 Å to about 18 Å, for example in the range of from 8 Å to about 16 Å, such as in the range of from 8 Å to about 14 Å, for example in the range of from 8 Å to about 12 Å, such as in the range of from 8 Å to about 10 Å.

Templated molecules

[0439] The templated molecules can be linked - or not linked - to the template having templated the synthesis of the templated molecule.

[0440] In one embodiment, the present invention relates to templated molecules comprising or essentially consisting of amino acids selected from the group consisting of α -amino acids, β -amino acids, γ -amino acids, ω -amino acids.

[0441] In various preferred embodiments the templated molecule comprises or essentially consists of one or more of natural amino acid residues, of α -amino acids, of monosubstituted α -amino acids, disubstituted α -amino acids, monosubstituted β -amino acids, disubstituted β -amino acids, or trisubstituted β -amino acids, tetrasubstituted β -amino acids, γ -amino acids, ω -amino acids, vinylogous amino acids, and N-substituted glycines.

[0442] The above-mentioned templated molecules comprising β -amino acids preferably have a backbone structure comprising or essentially consisting of a cyclohexane-backbone and/or a cyclopentane-backbone.

[0443] In other embodiments, the templated molecule comprises or essentially consists of molecules or molecular entities selected from the group of α -peptides, β -peptides, γ -peptides, ω -peptides, mono-, di- and tri-substituted α -peptides, β -peptides, γ -peptides, ω -peptides, peptides wherein the amino acid residues are in the L-form or in the D-form, vinylogous polypeptides, glycopoly-peptides, polyamides, vinylogous sulfonamide peptide, polysulfonamide, conjugated peptides comprising e.g. prosthetic groups, polyesters, polysaccharides, polycarbamates, polycarbonates, polyureas, polypeptidylphosphonates, polyurethanes, azatides, oligo N-substituted glycines, polyethers, ethoxyformacetal oligomers, poly-thioethers, polyethylene glycols (PEG), polyethylenes, polydisulfides, polyarylene sulfides, polynucleotides, PNAs, LNAs, morpholinos, oligo pyrrolinone, polyoximes, polyimines, polyethyleneimines, polyimides, poly-

acetals, polyacetates, polystyrenes, polyvinyl, lipids, phospholipids, glycolipids, polycyclic compounds comprising e.g. aliphatic or aromatic cycles, including polyheterocyclic compounds, proteoglycans, and polysiloxanes, including any combination thereof.

[0444] Neighbouring residues of the templated molecules according to the invention can be linked by a chemical bond selected from the group of chemical bonds consisting of peptide bonds, sulfonamide bonds, ester bonds, saccharide bonds, carbamate bonds, carbonate bonds, urea bonds, phosphonate bonds, urethane bonds, azatide bonds, peptoid bonds, ether bonds, ethoxy bonds, thioether bonds, single carbon bonds, double carbon bonds, triple carbon bonds, disulfide bonds, sulfide bonds, phosphodiester bonds, oxime bonds, imine bonds, imide bonds, including any combination thereof.

[0445] Also, the backbone structure of the templated molecules according to the invention can in one aspect comprise or essentially consist of a molecular group selected from -NHN(R)CO- ; -NHB(R)CO- ; -NHC(RR')CO- ; -NHC(=CHR)CO- ; $\text{-NHC}_6\text{H}_4\text{CO-}$; $\text{-NHCH}_2\text{CHRCO-}$; $\text{-NHCHRCH}_2\text{CO-}$; $\text{-COCH}_2\text{-}$; -COS- ; -CONR- ; -COO- ; -CSNH- ; $\text{-CH}_2\text{NH-}$; $\text{-CH}_2\text{CH}_2\text{-}$; $\text{-CH}_2\text{S-}$; $\text{-CH}_2\text{SO-}$; $\text{-CH}_2\text{SO}_2\text{-}$; $\text{-CH(CH}_3\text{)S-}$; -CH=CH- ; -NHCO- ; -NHCONH- ; -CONHO- ; $\text{-C(=CH}_2\text{)CH}_2\text{-}$; $\text{-PO}_2\text{NH-}$; $\text{-PO}_2\text{CH}_2\text{-}$; $\text{-PO}_2\text{CH}_2\text{N}^+\text{-}$; $\text{-SO}_2\text{NH-}$; and lactams, including any combination thereof.

[0446] In other embodiments of the invention, the templated molecules are not of polymeric nature.

[0447] The precursor is in one embodiment preferably selected from the group of precursors consisting of α -amino acid precursors, β -amino acid precursors, γ -amino acid precursors, and ω -amino acid precursors.

[0448] In some embodiment, the templated molecule is an oligomer or a polymer comprising at least one repetitive sequence of functional groups, such as at least three functional groups repeated at least twice in the templated molecule. The templated molecules also includes molecules wherein any sequence of at least three functional groups occurs only once.

[0449] Some preferred templated molecules preferably comprise or essentially consist of at least 2 different functional groups, such as at least 3 different functional groups, for example at least 4 different functional groups, such as at least 5 different functional groups, for example at least 6 different functional groups, such as at least 7 different functional groups, for example at least 8 different functional groups, such as at least 9 different functional groups, for example at least 10 different functional groups, such as more than 10 different functional groups. The functional groups can also be identical.

[0450] In one preferred aspect of the invention there is provided a templated molecule comprising a polymer comprising a plurality of covalently linked functional groups each comprising at least one residue, wherein the plurality of residues is preferably from 2 to 200, for example from 2 to 100, such as from 2 to 80, for example from 2 to 60, such as from 2 to 40, for example from 2 to 30, such as from 2 to 20, for example from 2 to 15, such as from 2 to 10, such as from 2 to 8, for example from 2 to 6, such as from 2 to 4, for example 2, such as from 3 to 100, for example from 3 to 80, such as from 3 to 60, such as from 3 to 40, for example from 3 to 30, such as from 3 to 20, such as from 3 to 15, for example from 3 to 10, such as from 3 to 8, for example from 3 to 6, such as from 3 to 4, for example 3, such as from 4 to 100, for example from 4 to 80, such as from 4 to 60, such as from 4 to 40, for example from 4 to 30, such as from 4 to 20, such as from 4 to 15, for example from 4 to 10, such as from 4 to 8, such as from 4 to 6, for example 4, for example from 5 to 100, such as from 5 to 80, for example from 5 to 60, such as from 5 to 40, for example from 5 to 30, such as from 5 to 20, for example from 5 to 15, such as from 5 to 10, such as from 5 to 8, for example from 5 to 6, for example 5, such as from 6 to 100, for example from 6 to 80, such as from 6 to 60, such as from 6 to 40, for example from 6 to 30, such as from 6 to 20, such as from 6 to 15, for example from 6 to 10, such as from 6 to 8, such as 6, for example from 7 to 100, such as from 7 to 80, for example from 7 to 60, such as from 7 to 40, for example from 7 to 30, such as from 7 to 20, for example from 7 to 15, such as from 7 to 10, such as from 7 to 8, for example 7, for example from 8 to 100, such as from 8 to 80, for example from 8 to 60, such as from 8 to 40, for example from 8 to 30, such as from 8 to 20, for example from 8 to 15, such as from 8 to 10, such as 8, for example 9, for example from 10 to 100, such as from 10 to 80, for example from 10 to 60, such as from 10 to 40, for example from 10 to 30, such as from 10 to 20, for example from 10 to 15, such as from 10 to 12, such as 10, for example from 12 to 100, such as from 12 to 80, for example from 12 to 60, such as from 12 to 40, for example from 12 to 30, such as from 12 to 20, for example from 12 to 15, such as from 14 to 100, such as from 14 to 80, for example from 14 to 60, such as from 14 to 40, for example from 14 to 30, such as from 14 to 20, for example from 14 to 16, such as from 16 to 100, such as from 16 to 80, for example from 16 to 60, such as from 16 to 40, for example from 16 to 30, such as from 16 to 20, such as from 18 to 100, such as from 18 to 80, for example from 18 to 60, such as from 18 to 40, for example from 18 to 30, such as from 18 to 20, for example from 20 to 100, such as from 20 to 80, for example from 20 to 60, such as from 20 to 40, for example from 20 to 30, such as from 20 to 25, for example from 22 to 100, such as from 22 to 80, for example from 22 to 60, such as from 22 to 40, for example from 22 to 30, such as from 22 to 25, for example from 25 to 100, such as from 25 to 80, for example from 25 to 60, such as from 25 to 40, for example from 25 to 30, such as from 30 to 100, for example from 30 to 80, such as from 30 to 60, for example from 30 to 40, such as from 30 to 35, for example from 35 to 100, such as from 35 to 80, for example from 35 to 60, such as from 35 to 40, for example from 40 to 100, such as from 40 to 80, for example from 40 to 60, such as from 40 to 50, for example from 40 to 45, such as from 45 to 100, for

example from 45 to 80, such as from 45 to 60, for example from 45 to 50, such as from 50 to 100, for example from 50 to 80, such as from 50 to 60, for example from 50 to 55, such as from 60 to 100, for example from 60 to 80, such as from 60 to 70, for example from 70 to 100, such as from 70 to 90, for example from 70 to 80, such as from 80 to 100, for example from 80 to 90, such as from 90 to 100.

[0451] In another preferred aspect of the invention there is provided a templated molecule comprising a polymer comprising a plurality of covalently linked functional groups each comprising a residue, wherein the covalently linked residues are capable of generating a polymer comprising, exclusively or in combination with additional portions, at least one portion selected from the group of polymer portions consisting of α -peptides, β -peptides, γ -peptides, ω -peptides, mono-, di- and tri-substituted α -peptides, β -peptides, γ -peptides, ω -peptides, peptides wherein the amino acid residues are in the L-form or in the D-form, vinylogous polypeptides, glycopoly-peptides, polyamides, vinylogous sulfonamide peptides, polysulfonamides, conjugated peptides comprising e.g. prosthetic groups, polyesters, polysaccharides, polycarbamates, polycarbonates, polyureas, polypeptidylphosphonates, polyurethanes, azatides, oligo N-substituted glycines, polyethers, ethoxyformacetal oligomers, poly-thioethers, polyethylene glycols (PEG), polyethylenes, polydisulfides, polyarylene sulfides, polynucleotides, PNAs, LNAs, morpholinos, oligo pyrrolinones, polyoximes, polyimines, polyethyleneimines, polyimides, polyacetals, polyacetates, polystyrenes, polyvinyl, lipids, phospholipids, glycolipids, polycyclic compounds comprising e.g. aliphatic or aromatic cycles, including polyheterocyclic compounds, proteoglycans, and polysiloxanes, and wherein the plurality of residues is preferably from 2 to 200, for example from 2 to 100, such as from 2 to 80, for example from 2 to 60, such as from 2 to 40, for example from 2 to 30, such as from 2 to 20, for example from 2 to 15, such as from 2 to 10, such as from 2 to 8, for example from 2 to 6, such as from 2 to 4, for example 2, such as from 3 to 100, for example from 3 to 80, such as from 3 to 60, such as from 3 to 40, for example from 3 to 30, such as from 3 to 20, such as from 3 to 15, for example from 3 to 15, such as from 3 to 10, such as from 3 to 8, for example from 3 to 6, such as from 3 to 4, for example 3, such as from 4 to 100, for example from 4 to 80, such as from 4 to 60, such as from 4 to 40, for example from 4 to 30, such as from 4 to 20, such as from 4 to 15, for example from 4 to 10, such as from 4 to 8, such as from 4 to 6, for example 4, for example from 5 to 100, such as from 5 to 80, for example from 5 to 60, such as from 5 to 40, for example from 5 to 30, such as from 5 to 20, for example from 5 to 15, such as from 5 to 10, such as from 5 to 8, for example from 5 to 6, for example 5, such as from 6 to 100, for example from 6 to 80, such as from 6 to 60, such as from 6 to 40, for example from 6 to 30, such as from 6 to 20, such as from 6 to 15, for example from 6 to 10, such as from 6 to 8, such as 6, for example from 7 to 100, such as from 7 to 80, for example from 7 to 60, such as from 7 to 40, for example from 7 to 30, such as from 7 to 20, for example from 7 to 15, such as from 7 to 10, such as from 7 to 8, for example 7, for example from 8 to 100, such as from 8 to 80, for example from 8 to 60, such as from 8 to 40, for example from 8 to 30, such as from 8 to 20, for example from 8 to 15, such as from 8 to 10, such as 8, for example 9, for example from 10 to 100, such as from 10 to 80, for example from 10 to 60, such as from 10 to 40, for example from 10 to 30, such as from 10 to 20, for example from 10 to 15, such as from 10 to 12, such as 10, for example from 12 to 100, such as from 12 to 80, for example from 12 to 60, such as from 12 to 40, for example from 12 to 30, such as from 12 to 20, for example from 12 to 15, such as from 14 to 100, such as from 14 to 80, for example from 14 to 60, such as from 14 to 40, for example from 14 to 30, such as from 14 to 20, for example from 14 to 16, such as from 16 to 100, such as from 16 to 80, for example from 16 to 60, such as from 16 to 40, for example from 16 to 30, such as from 16 to 20, such as from 18 to 100, such as from 18 to 80, for example from 18 to 60, such as from 18 to 40, for example from 18 to 30, such as from 18 to 20, for example from 20 to 100, such as from 20 to 80, for example from 20 to 60, such as from 20 to 40, for example from 20 to 30, such as from 20 to 25, for example from 22 to 100, such as from 22 to 80, for example from 22 to 60, such as from 22 to 40, for example from 22 to 30, such as from 22 to 25, for example from 25 to 100, such as from 25 to 80, for example from 25 to 60, such as from 25 to 40, for example from 25 to 30, such as from 30 to 100, for example from 30 to 80, such as from 30 to 60, for example from 30 to 40, such as from 30 to 35, for example from 35 to 100, such as from 35 to 80, for example from 35 to 60, such as from 35 to 40, for example from 40 to 100, such as from 40 to 80, for example from 40 to 60, such as from 40 to 50, for example from 40 to 45, such as from 45 to 100, for example from 45 to 80, such as from 45 to 60, for example from 45 to 50, such as from 50 to 100, for example from 50 to 80, such as from 50 to 60, for example from 50 to 55, such as from 60 to 100, for example from 60 to 80, such as from 60 to 70, for example from 70 to 100, such as from 70 to 90, for example from 70 to 80, such as from 80 to 100, for example from 80 to 90, such as from 90 to 100.

[0452] The templated molecule in one embodiment is preferably one, wherein the covalently linked residues are capable of generating a polymer comprising, exclusively or in combination with additional portions selected from the group, at least one portion selected from the group of polymer portions consisting of α -peptides, β -peptides, γ -peptides, ω -peptides, mono-, di- and tri-substituted α -peptides, β -peptides, γ -peptides, ω -peptides, peptides wherein the amino acid residues are in the L-form or in the D-form, and vinylogous polypeptides.

[0453] In one particular embodiment, the templated molecule is one wherein the covalently linked residues are capable of generating a polysaccharide.

[0454] In another aspect there is provided a templated molecule comprising a sequence of functional groups, wherein neighbouring functional groups are linked by a molecular moiety that is not natively associated with said functional groups.

[0455] Additional aspect of the present invention relates to i) a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule does not comprise or consist of an α -peptide or a nucleotide, ii) a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule does not comprise or consist of a monosubstituted α -peptide or a nucleotide, and iii) a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule does not comprise or consist of a peptide or a nucleotide.

Compositions of Templated Molecules

[0456] The templated molecules according to the invention, including those mentioned herein immediately above, can be present in a composition of templated molecules, wherein said composition comprises a plurality of more than or about 10^3 different templated molecules, such as more than or about 10^4 different templated molecules, for example more than or about 10^5 different templated molecules, such as more than or about 10^6 different templated molecules, for example more than or about 10^7 different templated molecules, such as more than or about 10^8 different templated molecules, for example more than or about 10^9 different templated molecules, such as more than or about 10^{10} different templated molecules, for example more than or about 10^{11} different templated molecules, such as more than or about 10^{12} different templated molecules, for example more than or about 10^{13} different templated molecules, such as more than or about 10^{14} different templated molecules, for example more than or about 10^{15} different templated molecules, such as more than or about 10^{16} different templated molecules, for example more than or about 10^{17} different templated molecules, such as more than or about 10^{18} different templated molecules.

[0457] The composition in some embodiments preferably further comprises the template capable of templating each templated molecule, or a subset thereof. Accordingly, in one preferred aspect of the present invention, there is provided i) a composition comprising a templated molecule and the template capable of templating the templated molecule, or ii) a composition comprising a templated molecule and the template that templated the synthesis of the templated molecule.

[0458] Various preferred features of the templated molecules either i) linked to the template capable of templating the synthesis of the templated molecule, or ii) present in a composition further comprising the template capable of templating the synthesis of the templated molecule is listed herein immediately below.

[0459] When being present in such compositions, it is preferred that i) the template does not consist exclusively of natural nucleotides, when the templated molecule is a peptide comprising exclusively monosubstituted α -amino acids, ii) the template is not a natural nucleotide, when the templated molecule is a natural α -peptide, iii) the template is not a nucleotide, when the templated molecule is a natural α -peptide, iv) the template is not a nucleotide, when the templated molecule is a monosubstituted α -peptide, v) the template is not a nucleotide, when the templated molecule is an α -peptide, vi) the template is not a natural nucleotide, when the templated molecule is a peptide, and vii) the template is not a nucleotide, when the templated molecule is a peptide.

Templated Molecules Linked to the Template that Templated the Synthesis of the Templated Molecule

[0460] In one preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the templated molecule does not comprise or consist of an α -peptide

[0461] In another preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the templated molecule does not comprise a monosubstituted α -peptide.

[0462] In yet another preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the templated molecule does not comprise or consist of an α -peptide or a nucleotide.

[0463] In a still further aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the template is not a natural nucleotide, when the templated molecule is an α -peptide.

[0464] In a still further preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the template does not consist exclusively of natural nucleotides, when the templated molecule is a peptide comprising exclusively mono-

substituted α -amino acids.

[0465] In a still further preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the template is not a natural nucleotide, when the templated molecule is a natural α -peptide.

[0466] In an even further preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the template is not a nucleotide, when the templated molecule is a natural α -peptide.

[0467] In a still further preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the template is not a nucleotide, when the templated molecule is a monosubstituted α -peptide.

[0468] In a still further preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the template is not a nucleotide, when the templated molecule is an α -peptide.

[0469] In a still further preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the template is not a natural nucleotide, when the templated molecule is a peptide.

[0470] In a still further preferred aspect of the present invention there is provided a templated molecule comprising a sequence of covalently linked, functional groups, wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, wherein the template is not a nucleotide, when the templated molecule is a peptide.

[0471] The templated molecule can be obtained according to the methods described herein above.

[0472] In even further aspects there is provided

i) a templated molecule comprising a sequence of covalently linked building blocks;

ii) a templated molecule comprising a sequence of covalently linked building blocks, wherein the sequence of covalently linked building blocks comprises a sequence of complementing elements forming a complementing template capable of complementing the template that templated the synthesis of the templated molecule, and wherein the templated molecule is linked to the complementing template or template that templated its synthesis; and

iii) a templated molecule according to any of the previous claims, wherein the templated molecule comprises a sequence of functional entities comprising at least one functional group, and optionally at least one reactive group type II, and wherein each functional entity is linked to a complementing element or a template that templated the synthesis of the templated molecule.

Uses of Templated Molecules

[0473] The templated molecules according to the present invention can be used for a variety of commercial purposes.

[0474] In one aspect, there is provided a method for screening templated molecules potentially having a predetermined activity, said method comprising the step of providing a target molecule or a target entity, including a surface, and obtaining templated molecules having an affinity for - or an effect on - said target molecule or target entity.

[0475] Another aspect relates to a method for assaying an activity potentially associated with a templated molecules, said method comprising the step of providing a target molecule or a target entity, including a surface, and obtaining templated molecules having an affinity for - or an effect on - said target molecule or target entity, and determining the activity of the templated molecule.

[0476] Yet another aspect provides a method for selecting complexes or templated molecules having a predetermined activity, said method comprising the step of performing a selection procedure and selecting templated molecules based on predetermined selection criteria.

[0477] There is also provided a method for screening a composition of molecules having a predetermined activity comprising:

i) establishing a first composition of templated molecules as described herein, or produced as defined herein by any method for preparing templated molecules,

ii) exposing the first composition to conditions enriching said first composition with templated molecules having the

predetermined activity, and

iii) optionally amplifying the templated molecules of the enriched composition obtaining a second composition,

iv) further optionally repeating step ii) to iii), and

v) obtaining a further composition having a higher ratio of templated molecules having the specific predetermined activity.

[0478] In one embodiment, the method further comprises a step of mutating the templated molecules, wherein said mutagenesis can take place prior to carrying out step iii), simultaneously with carrying out step iii), or after carrying out step iii). The mutagenesis can be carried out as random or site-directed mutagenesis.

[0479] Step iii) of the method preferably comprises a 10^1 to 10^{15} -fold amplification, and steps ii) and iii) can be repeated, such as at least 2 times, 3 times, 5 times, or at least 10 times, such as at least 15 times.

[0480] The method can comprise a further step of identifying the templated molecule having the predetermined activity, and said identification can be conducted e.g. by analysing the template and/or complementary template physically or by other means associated with the molecule.

[0481] The conditions enriching the first composition can comprise the further providing a binding partner to said templated molecule having the predetermined activity, wherein said binding partner is directly or indirectly immobilised on a support.

[0482] The conditions enriching the composition can involve any state of the art method, including any one or more of electrophoretic separation, gel filtration, immunoprecipitation, isoelectric focusing, centrifugation, and immobilization. The conditions enriching the composition can also comprise the further step of providing cells capable of internalising the templated molecule, or performing any interaction with the templated molecule having the predetermined activity.

[0483] The predetermined activity of the templated molecule is preferably an enzymatic activity or a catalytic activity.

[0484] In another aspect there is provided a method for amplifying the complementing template or the template that templated the synthesis of the templated molecule having, or potentially having a predetermined activity, said method comprising the step of contacting the template with amplification means, and amplifying the template. The method for amplifying the complementing template or the template that templated the synthesis of the templated molecule having, or potentially having, a predetermined activity, preferably comprises the steps of i) contacting the template with amplification means, and amplifying the template, and ii) obtaining the templated molecule in an at least two-fold increased amount.

[0485] In another aspect there is provided a method for altering the sequence of a templated molecule, including generating a templated molecule comprising a novel or altered sequence of functional groups, wherein said method preferably comprises the steps of

i) providing a first complementing template or a first template capable of templating the first templated molecule, or a plurality of such first complementing templates or first templates capable of templating a plurality of first templated molecules,

ii) mutating or modifying the sequence of the first complementing template or the first template, or the plurality of first complementing templates or first templates, and generating a second template or a second complementing template, or a plurality of second templates or second complementing templates, wherein said second template(s) or complementing template(s) is capable of templating the synthesis of a second templated molecule, or a plurality of second templated molecules, wherein said second templated molecule(s) comprises a sequence of covalently linked, functional groups that is not identical to the sequence of functional groups of the first templated molecule(s), and optionally

iii) templating by means of said second template(s) or complementing template(s) a second templated molecule, or a plurality of such second templated molecules.

[0486] In yet another aspect there is provided a method for altering the sequence of a templated molecule, including generating a templated molecule comprising a novel or altered sequence of functional groups, wherein said method preferably comprises the steps of

i) providing a plurality of first complementing templates or first templates capable of templating a plurality of first templated molecules,

ii) recombining the sequences of the plurality of first complementing templates or first templates, and generating a second template or a second complementing template, or a plurality of second templates or second complementing templates,

wherein said second template(s) or complementing template(s) is capable of templating the synthesis of a second templated molecule, or a plurality of second templated molecules,

wherein said second templated molecule(s) comprises a sequence of covalently linked, functional groups that is not identical to the sequence of functional groups of the first templated molecule(s), and optionally

iii) templating by means of said second template(s) or complementing template(s) a second templated molecule, or a plurality of such second templated molecules.

[0487] The methods can preferably comprise the further step of amplifying the complementing template or the template that templated the synthesis of the templated molecule, wherein said amplification step taking place prior to, simultaneously with, or after the step of mutagenesis or recombination.

[0488] When mutagenesis is used, it can be used as either site-directed mutagenesis, cassette mutagenesis, chemical mutagenesis, unique site-elimination (USE), error-prone PCR, error-prone DNA shuffling. Mutagenesis preferably involves DNA shuffling and/or any form of recombination including homologous recombination either in vivo or in vitro.

Variants and functional equivalents of templated molecules

[0489] The present invention is also directed to any variant and functional equivalent of a templated molecule. The variants and functional equivalents may be obtained by any state-of-the-art-method for modifying templated molecules in the form of polymers, including peptides.

[0490] In the context of the templated molecules of the present invention, molecules are said to be homologous if they contain similar backbone structures and/or similar functional groups. Functional groups, or molecular entities of functional groups, are divided into three homology groups: The charged functional groups, the hydrophobic groups, and the hydrophilic groups. When a functional group includes two or three molecular entities belonging to different homology groups, the functional group is said to belong to the two or three different homology groups.

[0491] Homology is measured in percent (%). As an example, the sequences AABBCA-CAAA and BBAACACBBB (where A, B and C denotes a functional group belonging to homology group A, B, and C, respectively) are 30 percent homologous.

Examples

Example 1 to 7: Preparation of the mononucleotide building block (1)

[0492] Building block I may be prepared according to the general scheme shown below:

Example 1: Preparation of 3-*tert*-Butoxycarbonylamino-propionic acid (*N*-Boc- β -alanine)(1a)**[0493]**

[0494] To a solution of β -alanine (2.25 g, 25 mmol) in aq. NaHCO_3 (25 mL) were added di-*tert*-butyl dicarbonate (4.36 g, 20 mmol) and acetonitrile (25 mL). The reaction mixture was stirred at room temperature for 18 h.

EtOAc (100 mL) was added and pH was adjusted to 4-5 by addition of NaH_2PO_4 . The product was extracted into EtOAc (3 x 50 mL), dried (Na_2SO_4), and evaporated to dryness under vacuum to afford 3.71 g (98%)

^1H NMR (CDCl_3) δ 11 (1 H, br s, COOH), 5.07 (1 H, br s, NH), 3.40 (2H, m), 2.58 (2H, m), 1.44 (9H, s, $t\text{Bu}$).

Example 2: Preparation of *N*-Boc- β -alanine propargyl ester(1b).**[0495]**

[0496] *N*-Boc- β -alanine (1.91 g, 10.1 mmol) and propargyl alcohol (0.675 g, 12 mmol) were dissolved in EtOAc (25 mL). Dicyclohexyl-carbodiimide (DCC, 2.06 g, 10 mmol) was added to the solution and after 16 h of stirring at room temperature, the reaction mixture was filtered and evaporated to dryness under vacuum. Crude product yield

Example 3: Preparation of 5-Iodo-2'-deoxyuridine 3',5'-Di-*tert*-butyldimethylsilyl Ether(1c).**[0497]**

[0498] 5-Iodo-2'-deoxyuridine (Aldrich, 2.39 g, 6.7 mmol) and imidazole (2.025 g, 29.7 mmol) was dissolved in anhydrous DMF (10 mL). A solution of *tert*-butyldimethylsilyl chloride (2.24 g, 14.9 mmol) in anhydrous DMF (5 mL) was added and the resulting mixture was stirred for 16 h at room temperature.

The reaction mixture was poured into EtOAc (400 mL), washed with NH_4Cl (50% sat. aq, 80 mL) followed by water (80 mL). After drying with Na_2SO_4 , EtOAc was removed under reduced pressure to leave a colourless oil that solidified on standing. Recrystallization in n-hexane (14 mL) afforded 2.64 g, 80%.

^1H NMR (CDCl_3) δ 8.18 (1H, br s, NH); 8.10 (1H, s); 6.23 (1H, dd); 4.40 (1 H, dt); 4.05 (1 H, dd); 3.92 (1 H, dd); 3.78 (1H, dd); 2.32 (1 H, ddd); 2.05 (1 H, ddd); 0.95(9H, s, $t\text{Bu}$); 0.90(9H, s, $t\text{Bu}$); 0.15 (3H, s, CH_3); 0.13 (3H, s, CH_3); 0.08 (3H, s, CH_3); 0.07 (3H, s, CH_3).

Example 4: Preparation of compound (1d)

[0499]

Compound (1d)

[0500] A solution of iodo silyl ether (1c) (1.62 g, 2.7 mmol), *N*-Boc- β -alanine(1a) (2.03 g, 8.9 mmol) and triethylamine (0.585 g, 5.8 mmol) in 10 mL dry DMF were stirred at room temperature. N_2 was passed through the solution for 20 min. Tetrakis(triphenylphosphine)palladium(0) (269 mg, 0.2 mmol) and copper(I) iodide (90 mg, 0.4 mmol) were added and the reaction mixture was stirred at room temperature for 32 h.

EtOAc (100 mL) was poured into the reaction mixture, followed by washing (aq Na-HCO₃ (50 mL); brine (50 mL)), drying (Na₂SO₄), and removal of solvent by vacuum evaporation.

The crude product (2.4 g) was purified by silica column chromatography eluting with EtOAc:Heptane gradient (1:2)-(5:3) (v/v). Product yield 1.15 g, 60%.

¹H NMR (CDCl₃) δ 8.45 (1 H, s), 8.05 (1 H, s, 6-H), 7.35 (1H, bs, NH), 6.25 (1H, dd, 1'-H), 4.82 (2H, s, CH₂O), 4.39 (1H, m, 3'-H), 3.97 (1H, m, 4'-H), 3.80 (2H, dd, 5',5''-H), 3.40 (2H, m, CH₂N), 2.58 (2H, t, CH₂), 2.2 (1 H, m, 2'-H), 2.0 (1H, m, 2''-H), 1.45 (9H, s, ^tBu), 0.93 (9H, s, ^tBu), 0.89 (9H, s, ^tBu), 0.15 (3H, s, CH₃), 0.13 (3H, s, CH₃), 0.08 (3H, s, CH₃), 0.07 (3H, s, CH₃).

Example 5: Preparation of compound (1e)

[0501]

Compound (1e)

[0502] A solution of *N*-Boc- β -alanine silyl ether (1d) (100 mg, 0.15 mmol), glacial acetic acid (75 mg, 1.25 mmol) and tetrabutylammonium fluoride trihydrate (TBAF) (189 mg, 0.6 mmol) in 2 mL dry THF was stirred at room temperature for 3 d.

The reaction mixture was evaporated and purified by silica column chromatography eluting with dichloromethane(DCM): methanol(MeOH) gradient (95:5)-(88:12) (v/v). Product yield 26 mg, 38%.

¹H NMR (CD₃OD) δ 8.35 (1H, s, 6-H), 6.15 (1H, t, 1'-H), 4.80 (2H, s, CH₂O), 4.32 (1H, dt, 3'-H), 3.86 (1H, q, 4'-H), 3.70 (2H, dd, 5',5''-H), 3.24 (2H, m, CH₂N), 2.47 (2H, t, CH₂), 2.28-2.10 (1H, m, 2',2''-H), 1.44 (9H, s, ^tBu).

Example 6: Preparation of compound (1f)**[0503]****COMPOUND 1f**

[0504] *N*-Boc- β -alanine nucleoside (1e) (26 mg, 57 μ mol) was dissolved in 200 μ L dry trimethylphosphate. After cooling to 0 °C, a solution of phosphorus oxychloride (POCl_3) in dry trimethylphosphate was added (100 μ L stock solution (104 mg/mL), 68 μ mol). The reaction mixture was stirred at 0 °C for 2h.

Subsequently a solution of tributylammonium pyrophosphate (Sigma P-8533) (67.8 mg, 143 μ mol in 300 μ L dry DMF) and tributylamine (26.9 mg, 145 μ mol in 150 μ L dry DMF) was added at 0 °C. The reaction was stirred at room temperature for 3 min. and then stopped by addition of 1 mL 1.0 M triethylammonium hydrogencarbonate.

Example 7: Preparation of compound I**[0505]****COMPOUND I**Removal of *N*-Boc protection group.

[0506] Following phosphorylation, 50 μ L of the phosphorylation reaction mixture is adjusted to pH = 1 using HCl and incubated at room temperature for 30 minutes. The mixture is adjusted to pH 5.5 using equimolar NaOH and Na-acetate (pH 5.5) before purification on TLC.

Purification of nucleotide derivatives using thin-layer chromatography (TLC)

[0507] From the crude mixture, 20 samples of 2 μ L were spotted on kieselgel 60 F₂₅₄ TLC (Merck). Organic solvents and non-phosphorylated nucleosides were separated from the nucleotides derivatives using 100% methanol as running solution. Subsequently, the TLC plate is air-dried and the nucleotide-derivative identified by UV-shadowing. Kiesel containing the nucleotide-derivative was isolated and extracted twice using 10 mM Na-acetate (pH = 5.5) as solvent. Kieselgel was removed by centrifugation and the supernatant was dried *in vacuo*. The nucleotide derivative was resuspended in 50-100 μ L H₂O to a final concentration of 1-3 mM. The concentration of each nucleotide derivative was evaluated by UV-absorption prior to use in polymerase extension reactions.

Examples 8 to 13: Preparation of the mononucleotide building block (II)

[0508] Building block II may be prepared according to the general scheme shown below:

Example 8: Preparation of *N*-Boc-3-phenyl-β-alanine (2a).

[0509]

COMPOUND 2a

[0510] To a solution of 3-amino-3-phenylpropionic acid (3.30 g, 20 mmol) in NaHCO₃ (50% sat. aq, 25 mL) were added di-*tert*-butyl dicarbonate (4.36 g, 20 mmol) and acetonitrile (30 mL). The reaction mixture was stirred at room temperature for 18 h. Di-*tert*-butyl dicarbonate (4.36 g, 20 mmol) was added and the reaction mixture was stirred at room temperature for 18 h.

EtOAc (100 mL) was added and pH was adjusted to 4-5 by addition of NaH₂PO₄. The product was extracted into EtOAc (3 x 100 mL), dried (Na₂SO₄), and evaporated to dryness under vacuum to afford crude product 5.6 g (105%)

Example 9: Preparation of 5-(3-Hydroxypropyn-1-yl)-2'-deoxyuridine 3',5'-Di-*tert*-butyldimethylsilyl Ether(2b).

[0511]

COMPOUND 2b

[0512] A solution of iodo silyl ether (3) (1.30 g, 2.2 mmol), propargyl alcohol (0.386 g, 6.9 mmol) and triethylamine (0.438 g, 4.3 mmol) in 7 mL dry DMF was deaeraed with N₂. Tetrakis(triphenylphosphine)palladium(0) (228 mg, 0.2 mmol) and copper(I) iodide (120 mg, 0.4 mmol) were added and the reaction mixture was stirred at room temperature for 32 h.

[0513] EtOAc (100 mL) was poured into the reaction mixture, followed by washing (aq Na-HCO₃ (50 mL); brine (50 mL)), drying (Na₂SO₄), and removal of solvent by vacuum evaporation.

The crude product (1.73 g) was purified by silica column chromatography eluting with EtOAc:Heptane gradient (2:3)-(3:2) (v/v). Product yield 0.713 g, 63%.

¹H NMR (CDCl₃) δ 8.47 (1H, s), 8.05 (1H, s, 6-H), 6.29 (1H, dd, 1'-H), 4.42 (2H, s, CH₂), 4.39 (1H, m, 3'-H), 3.98 (1H, m, 4'-H), 3.83 (2H, dd, 5',5''-H), 2.32 (1H, m, 2'-H), 2.02 (1H, m, 2''-H), 0.93 (9H, s, ^tBu), 0.89 (9H, s, ^tBu), 0.15 (3H, s, CH₃), 0.13 (3H, s, CH₃), 0.08 (3H, s, CH₃), 0.07 (3H, s, CH₃).

Example 10: Preparation of compound (2c)

[0514]

COMPOUND 2c

[0515] *N*-Boc-3-phenyl- β -alanine (8) (265 mg, 1.0 mmol) and compound (2b) (255 mg, 0.5 mmol) were dissolved in THF (15 mL). Diisopropyl-carbodiimide (DIC, 126 mg, 1 mmol) and 4-dimethylaminopyridin (DMAP, 10 mg) were added to the solution, and after 16 h of stirring at room temperature the reaction mixture was poured into EtOAc (100 mL), washed with NaHCO₃ (50% sat. aq, 50 mL), dried (Na₂SO₄), filtered and evaporated under vacuum.

The crude product was purified by silica column chromatography eluting with EtOAc:Heptane gradient (1:2)-(2:3) (v/v). Product yield 335 mg, 88%.

¹H NMR (CDCl₃) δ 8.49 (1H, s), 8.04 (1H, s, 6-H), 7.29 (5H, m, Ph), 6.27 (1H, dd, 1'-H), 5.5 (1H, bd), 5.09 (1H, m), 4.80 (2H, s, CH₂), 4.39 (1H, m, 3'-H), 3.98 (1H, m, 4'-H), 3.82 (2H, dd, 5',5''-H), 2.87 (2H, d), 2.29 (1H, m, 2'-H), 2.01 (1H, m, 2''-H), 1.41 (9H, s, ^tBu), 0.91 (9H, s, ^tBu), 0.89 (9H, s, ^tBu), 0.15 (3H, s, CH₃), 0.13 (3H, s, CH₃), 0.08 (3H, s, CH₃), 0.07 (3H, s, CH₃).

Example 11: Preparation of compound 2d

[0516]

COMPOUND 2d

[0517] A solution of compound (2c) (334 mg, 440 μ mol), glacial acetic acid (190 mg, 3.15 mmol) and tetrabutylammonium fluoride trihydrate (TBAF) (500 mg, 1.58 mmol) in 6 mL dry THF was stirred at room temperature for 18 h.

The reaction mixture was evaporated and purified by silica column chromatography eluting with (DCM):(MeOH) gradient (95:5)-(9:1) (v/v). Product yield 122 mg, 52%.

¹H NMR (CDCl₃) δ 10.1 (1H, s), 8.24 (1H, s, 6-H), 7.3 (5H, m, Ph), 6.37 (1H, dd, 1'-H), 5.6 (1H, bs), 5.09 (1H, m), 4.79 (2H, s, CH₂), 4.52 (1H, m, 3'-H), 4.0 (1H, m, 4'-H), 3.85 (2H, dd, 5',5''-H), 2.87 (2H, d), 2.4 (1H, m, 2'-H), 2.25 (1H, m, 2''-H), 1.4 (9H, s, ^tBu).

Example 12: Preparation of compound (2e):

[0518]

COMPOUND 2e

[0519] Compound (2d) (122 mg, 230 μmol) was dissolved in 400 μL dry trimethylphosphate. After cooling to 0 $^{\circ}\text{C}$, a solution of phosphorus oxychloride (POCl_3) in dry trimethylphosphate was added (400 μL stock solution (105 mg/mL), 276 μmol). The reaction mixture was stirred at 0 $^{\circ}\text{C}$ for 2h. Subsequently a solution of tributylammonium pyrophosphate (273 mg, 576 μmol in 1.2 mL dry DMF) and tributylamine (109 mg, 587 μmol in 600 μL dry DMF) was added at 0 $^{\circ}\text{C}$. The reaction was stirred at room temperature for 10 min. and then stopped by addition of 1.0 M triethylammonium hydrogencarbonate (1 mL).

Example 13: Preparation of Compound II**[0520]**

COMPOUND II

Removal of *N*-Boc protection group.

[0521] Following phosphorylation, 50 μL of the phosphorylation reaction mixture is adjusted to pH = 1 using HCl and incubated at room temperature for 30 minutes. The mixture is adjusted to pH 5.5 using equimolar NaOH and Na-acetate (pH 5.5) before purification on TLC.

Purification of nucleotide derivatives using thin-layer chromatography (TLC)

[0522] From the crude mixture, 20 samples of 2 μL were spotted on kieselgel 60 F_{254} TLC (Merck). Organic solvents and non-phosphorylated nucleosides were separated from the nucleotides derivatives using 100% methanol as running solution. Subsequently, the TLC plate is air-dried and the nucleotide-derivative identified by UV-shadowing. Kiesel containing the nucleotide-derivative was isolated and extracted twice using 10 mM Na-acetate (pH = 5.5) as solvent. Kieselgel was removed by centrifugation and the supernatant was dried *in vacuo*. The nucleotide derivative was resuspended in 50-100 μL H_2O to a final concentration of 1-3 mM. The concentration of each nucleotide derivative was evaluated by UV-absorption prior to use in polymerase extension reactions.

Examples 14 to 18: Preparation of the mononucleotide building block (III)

[0523] Building block III may be prepared according to the general scheme shown below:

Example 14: Preparation of *N*-Boc-β-alanine propargyl amide(3a)

[0524]

COMPOUND 2a

[0525] *N*-Boc-β-alanine(1a) (1.05g, 5.5 mmol) and propargyl amine (0.90 g, 16.5 mmol) were dissolved in THF (10 mL). Diisopropyl-carbodiimide (DIC, 695 g, 5.5 mmol) was added and the reaction mixture was stirred for 16 h at room temperature. Water was added (20 mL) and the product was extracted into EtOAc (3x30 mL). The combined EtOAc was dried (Na₂SO₄) and evaporated. The crude product was purified by silica column chromatography eluting with EtOAc:Heptane gradient (2:3)-(3:2.5) (v/v). Product yield 0.925 g, 74 %.

¹H NMR (CDCl₃) δ 6.69 (1H, bs, NH), 5.32 (1H, bs, NH), 4.04 (2H, bs), 3.41 (2H, dd), 2.45 (2H, t), 2.24 (1H, s), 1.44 (9H, s, ^tBu).

Example 15: Preparation of compound (3b)

[0526]

COMPOUND 3b

[0527] A solution of 5-iodo-2'-deoxycytidine (176 mg, 0.5 mmol), *N*-Boc-β-alanine propargyl amide(14) and triethylamine (100 mg, 1.0 mmol) in dry DMF (5 mL) were stirred at room temperature. N₂ was passed through the solution for 20 min.

[0528] Tetrakis(triphenylphosphine)palladium(0) (66.5 mg, 0.057 mmol) and copper(I) iodide (20.7 mg, 0.108 mmol) were added and the reaction mixture was stirred at room temperature for 5 d

Imidazole (112 mg, 1.6 mmol) was added. A solution of *tert*-butyldimethylsilyl chloride (234 mg, 1.5 mmol) in anhydrous DMF (1 mL) was added and the resulting mixture was stirred for 16 h at room temperature.

The reaction mixture was evaporated and EtOAc (25 mL) was added. The resulting mixture was filtrated and the solvent removed by vacuum evaporation.

The crude product was purified by silica column chromatography eluting with DCM:MeOH (92.5-7.5) (v/v). Product yield 84 mg, 25%.

¹H NMR (CDCl₃) δ 8.13 (H, s), 6.21 (1H, dd, 1'-H), 4.66 (1H, m), 4.16 (2H, s, CH₂), 4.04-3.85 (4H, m), 3.35-3.31 (2H, m), 2.43-2.36 (2H, m), 2.12-1.99 (1 H, m), 1.44 (9H, s, ^tBu), 0.95 (9H, s, ^tBu), 0.92 (9H, s, ^tBu), 0.17 (3H, s, CH₃), 0.15 (3H, s, CH₃), 0.13 (3H, s, CH₃), 0.12 (3H, s, CH₃).

Example 16: Preparation of compound (3c)

[0529]

COMPOUND 3c

[0530] A solution of compound(3b) (84 mg, 0.12 mmol) and tetrabutylammonium fluoride trihydrate (TBAF) (155 mg, 0.45 mmol) in 2 mL dry THF was stirred at room temperature for 4 days.

The reaction mixture was evaporated and purified by silica column chromatography eluting with DCM:MeOH gradient (9:1)-(8:2) (v/v). Product yield 27 mg, 48%.

^1H NMR (CDCl_3) δ 8.32 (1H, s), 6.20 (1H, dd, 1'-H), 4.35 (1H, dt), 4.15 (2H, s, CH_2), 3.95 (1H, q), 3.83 (1H, dd), 3.72 (1H, dd), 3.36-3.30 (3H, m), 2.42-2.36 (3H, m), 2.13 (1H, dt), 1.40 (9H, s, ^tBu).

Example 17: Preparation of compound (3d)

[0531]

COMPOUND 3d

[0532] Compound (3c) (27 mg, 60 μmol) was dissolved in 100 μL dry trimethylphosphate. After cooling to 0 $^\circ\text{C}$, a solution of phosphorus oxychloride (POCl_3) in dry trimethylphosphate was added (100 μL stock solution (110 mg/mL), 72 μmol). The reaction mixture was stirred at 0 $^\circ\text{C}$ for 2h.

Subsequently a solution of tributylammonium pyrophosphate (71 mg, 150 μmol in 300 μL dry DMF) and tributylamine (28.3 mg, 153 μmol in 150 μL dry DMF) was added at 0 $^\circ\text{C}$. The reaction was stirred at room temperature for 3 min. and then stopped by addition of 1.0 M triethylammonium hydrogencarbonate (1 mL).

Example 18: Preparation of compound III

[0533]

COMPOUND III

Removal of *N*-Boc protection group.

[0534] Following phosphorylation, 50 μ l of the phosphorylation reaction mixture is adjusted to pH = 1 using HCl and incubated at room temperature for 30 minutes. The mixture is adjusted to pH 5.5 using equimolar NaOH and Na-acetate (pH 5.5) before purification on TLC.

Purification of nucleotide derivatives using thin-layer chromatography (TLC)

[0535] From the crude mixture, 20 samples of 2 μ l were spotted on kieselgel 60 F₂₅₄ TLC (Merck). Organic solvents and non-phosphorylated nucleosides were separated from the nucleotides derivatives using 100% methanol as running solution. Subsequently, the TLC plate is air-dried and the nucleotide-derivative identified by UV-shadowing. Kiesel containing the nucleotide-derivative was isolated and extracted twice using 10 mM Na-acetate (pH = 5.5) as solvent. Kieselgel was removed by centrifugation and the supernatant was dried *in vacuo*. The nucleotide derivative was resuspended in 50-100 μ l H₂O to a final concentration of 1-3 mM. The concentration of each nucleotide derivative was evaluated by UV-absorption prior to use in polymerase extension reactions.

Examples 19 to 22: Preparation of the mononucleotide building block (IV)

[0536] Building block IV may be prepared according to the general scheme shown below:

Example 19: Preparation of *N*-Acetyl- β -alanine(4a)**[0537]****COMPOUND 4a**

[0538] To a solution of β -alanine (2,25 g, 25 mmol) in aq. NaHCO_3 (15 mL) was added acetonitrile (15 mL) and acetic anhydride (2.55 g, 25 mmol). The reaction mixture was stirred at room temperature for 3 h. Acetic anhydride (2.55 g, 25 mmol) was added and after 2 h and pH was adjusted to 4-5 by addition of NaH_2PO_4 .

[0539] The product was extracted into EtOAc (3 x 50 mL), dried (Na_2SO_4) and evaporated to dryness under vacuum to afford 1.96 g (60%)

Example 20: Preparation of *N*-Acetyl- β -alanine propargyl ester(4b).**[0540]****COMPOUND 4b**

[0541] To a solution of *N*-Acetyl- β -alanine(4a) in THF (20 mL) was added propargyl alcohol (840 mg, 15 mmol), 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (EDC) (1.035 g, 5.39 mmol), triethylamine (540 mg, 5.4 mmol) and 4-dimethylaminopyridin (5 mg). The reaction mixture was stirred at room temperature for 2 d.

The reaction mixture was poured into EtOAc (100 mL), washed with NaH_2PO_4 (50% sat. aq, 2x50 mL) followed by NaHCO_3 (50% sat. aq, 50 mL). After drying (Na_2SO_4), EtOAc was removed under reduced pressure to leave a colourless oil that solidified on standing. Product yield 536 mg, 59%.

Example 21: Preparation of compound (4c)**[0542]****COMPOUND 4c**

[0543] A solution of 5-iodo-2'-deoxycytidin (200 mg, 0.56 mmol), triethylamine (100 mg, 1 mmol) and compound (4b) (190 mg, 1.13 mmol) in anhydrous DMF (7mL) was stirred at room temperature. N_2 was passed through the solution for 20 min.

[0544] Tetrakis(triphenylphosphine)palladium(0) (70mg, 0.06 mmol) and copper(I) iodide (22 mg, 0.12 mmol) were added and the reaction mixture was stirred at room temperature for 4 d.

EP 1 402 024 B1

The reaction mixture was evaporated and purified by silica column chromatography eluting with DCM:MeOH gradient (9:1)-(8:2) (v/v). Product yield 141 mg, 63%.

^1H NMR (CD_3OD) δ 8.41 (1H, s), 6.20 (1H, dd, 1'-H), 4.97 (2H, s), 4.38 (1H, dt), 3.97 (1H, q), 3.85 (1H, dd), 3.75 (1H, dd), 3.46 (2H, t), 2.61 (2H, t), 2.39 (1H, m), 2.18 (1H, m).

Example 22: Preparation of compound IV:

[0545]

COMPOUND IV

[0546] Compound (4c) (140 mg, 355 μmol) was dissolved in 600 μL dry trimethylphosphate. After cooling to 0 $^\circ\text{C}$, a solution of phosphorus oxychloride (POCl_3) in dry trimethylphosphate was added (600 μL stock solution (108 mg/mL), 420 μmol). The reaction mixture was stirred at 0 $^\circ\text{C}$ for 2h.

Subsequently a solution of tributylammonium pyrophosphate (422 mg, 890 μmol in 1.8 mL dry DMF) and tributylamine (168 mg, 900 μmol in 0.9 mL dry DMF) was added at 0 $^\circ\text{C}$. The reaction was stirred at room temperature for 3 min. and then stopped by addition of 1.0 M triethylammonium hydrogencarbonate (1 mL).

[0547] From the crude mixture, 20 samples of 2 μL were spotted on kieselgel 60 F_{254} TLC (Merck). Organic solvents and non-phosphorylated nucleosides were separated from the nucleotides derivatives using 100% methanol as running solution. Subsequently, the TLC plate is air-dried and the nucleotide-derivative identified by UV-shadowing. Kiesel containing the nucleotide-derivative was isolated and extracted twice using 10 mM Na-acetate (pH = 5.5) as solvent. Kieselgel was removed by centrifugation and the supernatant was dried *in vacuo*. The nucleotide derivative was resuspended in 50-100 μL H_2O to a final concentration of 1-3 mM. The concentration of each nucleotide derivative was evaluated by UV-absorption prior to use in polymerase extension reactions.

Examples 23 to 27: Preparation of the mononucleotide building block (V)

[0548] Building block V may be prepared according to the general scheme shown below:

Example 23: Preparation of 2-Aminoxy-acetic acid Ethyl ester (5a)

[0549]

COMPOUND 5a

[0550] Acetyl chloride (5 mL) was added to abs. ethanol (50 mL) and the solution was cooled to room temperature. 2-Aminooxy-acetic acid, hydrochloride (2:1) (1.10 g, 10 mmol) was added and the reaction mixture was stirred for 16 h at room temperature. The reaction mixture was evaporated, K_2CO_3 aq. (2M) (10 mL) was added and the product was extracted into diethyl ether (5x20 mL), dried (Na_2SO_4), and evaporated to afford 1.007 g, 84%. 1H NMR ($CDCl_3$) δ 4.24 (2H, s), 4.22 (2H, q), 1.30 (3H, t).

Example 24: Preparation of Pent-4-ynylaminooxy-acetic acid Ethyl ester (5b)

[0551]

COMPOUND 5b

[0552] To a solution of 2-Aminooxy-acetic acid ethyl ester (573 mg, 4.8 mmol) and 4-Pentynoic acid (441 mg, 4.5 mmol) in 15 mL EtOAc were added dicyclohexylcarbodiimide (928 mg, 4.5 mmol) and the resulting mixture was stirred at room temperature for 16 h.

The reaction mixture was filtered, and the filtrate was washed with EtOAc (2x5 mL). The combined EtOAc was washed with aq NaH_2PO_4 and aq $NaHCO_3$, dried (Na_2SO_4), and evaporated to afford 950 mg of crude product.

The crude product was purified by silica column chromatography eluting with EtOAc:Heptane gradient (1:3)-(1:1) (v/v).

Product yield 700 mg, 78%

1H NMR ($CDCl_3$) δ 4.41 (2H, s), 4.18 (2H, q), 2.77 (1 H, t), 2.34 (2H, dt), 2.17 (2H, bt), 1.40 (3H, t).

Example 25: Preparation of compound 5c.

[0553]

COMPOUND 5c

[0554] A solution of 7-Deaza-7-iodo-2'-deoxyadenosine (125 mg, 0.33 mmol), (prepared as described by Seela, F.; Synthesis 1996, 726-730), triethylamine (67 mg, 0.66 mmol) and compound (5b) (305 mg, 1.53 mmol) in anhydrous DMF (7 mL) was stirred at room temperature. N_2 was passed through the solution for 20 min. Tetrakis(triphenylphosphine)

EP 1 402 024 B1

palladium(0) (75mg, 0.065 mmol) and copper(I) iodide (24 mg, 0.33 mmol) were added and the reaction mixture was stirred at room temperature for 16 h.

The reaction mixture was evaporated and purified by silica column chromatography eluting with DCM:MeOH (9:1) (v/v). Product yield 129 mg, 86%.

¹H NMR (d⁶DMSO) δ 11.6 (1H, s), 8.09 (1H, s), 7.63 (1H, s), 6.47 (1H, dd), 5.26 (1H, d), 5.08 (1H, t), 4.42 (2H, s), 4.32 (1 H, m), 4.08 (2H, q), 3.81 (1H, m), 3.54 (2H, m), 2.66 (1 H, t), 2.46 (1H, m), 2.30 (2H, t), 2.15 (2H, ddd), 1.15 (3H, t).

Example 26: Preparation of compound 5d:

[0555]

COMPOUND 5d

[0556] Compound (5c) (117 mg, 260 μmol) was dissolved in 500 μL dry trimethylphosphate. After cooling to 0 °C, a solution of phosphorus oxychloride (POCl₃) in dry trimethylphosphate was added (400 μL stock solution (120 mg/mL), 310 μmol). The reaction mixture was stirred at 0 °C for 2h.

Subsequently a solution of tributylammoniumpyrophosphate (200 mg, 420 μmol in 1.00 mL dry DMF) and tributylamine (123.6 mg, 670 μmol in 500 μL dry DMF) was added at 0 °C. The reaction was stirred at room temperature for 3 min. and then stopped by addition of 1 mL 1.0 M triethylammoniumhydrogencarbonate.

Example 27: Preparation of compound V:

[0557]

COMPOUND V

[0558] The reaction mixture of compound (5d) (2.0 mL) was diluted with water (6.0 mL) and adjusted to pH 13 using NaOH (2M, aq). After incubation at 5 °C for 64 h, the reaction mixture was extracted with EtOAc (5x5 mL), adjusted to

pH 7.0 using HCl (2M, aq), evaporated and diluted with triethylammonium acetate buffer (500 μ L, 0.1 M aq). The crude product of triphosphate was purified by HPLC on a Waters Xterra MS C₁₈ Column, using the following buffer system: (A) aqueous triethylammonium acetate (0.1 M, pH 7) and (B) acetonitrile:water (80:20) containing triethylammonium acetate (0.1 M). The gradient time table contains 8 entries which are:

Time	A%	B%
0.00	98	2
1.00	98	2
10.00	90	10
16.00	85	15
18.00	65	35
20.00	0	100
25.00	0	100
25.10	100	0

[0559] Retention times of compound **V** and compound **5d** were 4.82 min and 7.29 min respectively, measured by monitoring UV absorbance at 260 nm. The fractions containing pure product were pooled and lyophilized two times from water (3 mL).

Examples 28 to 30: Preparation of the mononucleotide building block (VI)

Example 28: Preparation of Pent-4-ynoic acid 4-oxo-4H-benzo[d][1,2,3]triazin-3-yl ester (6a)

[0560]

[0561] Pentynoic acid (200 mg, 2.04 mmol) was dissolved in THF (4 mL). The solution was cooled in a brine-icewater bath. A solution of dicyclohexylcarbodiimide (421 mg, 2.04 mmol) in THF (2 mL) was added. 3-Hydroxy-1,2,3-benzotriazin-4(3H)-one (333 mg, 2.04 mmol) was added after 5 minutes. The reaction mixture was stirred 1 h at -10°C and then 2 h at room temperature. TLC indicated full conversion of 3-hydroxy-1,2,3-benzotriazin-4(3H)-one (eluent: ethyl acetate). Precipitated salts were filtered off. The filtrate was concentrated *in vacuo* and crystallized from hexane (4 mL). The crystals were filtered off and dried. Yield: 450 mg, 93%. R_F = 0.8 (ethyl acetate).

Example 29: Preparation of 2-Pent-4-ynoylamino-succinic acid 1-*tert*-butyl ester 4-isopropyl ester (6b)

[0562]

[0563] L-Aspartic acid α,β -di-*tert*-butyl ester hydrochloride (Novabiochem 04-12-5066, 200 mg, 0.71 mmol) was dissolved in THF (5 mL). The activated ester 6a (173 mg, 0.71 mmol) and diisopropylethylamine (0.15 mL, 0.86 mmol) were added. The mixture was stirred overnight. Dichloromethane (10 mL) was added. The organic phase was washed with citric acid (2 x 10 mL), saturated NaHCO_3 (aq, 10 mL), brine (10 mL), dried (Na_2SO_4) and concentrated to a syrup. An NMR spectrum indicated the syrup was pure enough for further synthesis. $^1\text{H-NMR}$ (CDCl_3): δ 6.6 (1H, NH), 4.6 (1H, CH), 2.8 (2H, CH_2), 2.4 (4H, 2 x CH_2), 1.9 (1 H, CH), 1.2 (18H, 6 x CH_3).

Example 30: Preparation of 2-[5-[1-(4-Hydroxy-5-(*O*-triphosphate-hydroxymethyl)-tetrahydrofuran-2-yl)-2,4-dioxo-1,2,3,4-tetrahydro-pyrimidin-5-yl]-pent-4-ynoylamino]-succinic acid di-*tert*-butyl ester (VI)

[0564]

[0565] The nucleotide (20 mg, 0.022 mmol) was dissolved in water-ethanol (1:1, 2 mL). The solution was degassed and kept under an atmosphere of argon. The catalyst $\text{Pd}(\text{PPh}_2(m\text{-C}_6\text{H}_5\text{SO}_3\text{Na}^+))_4$ (20 mg, 0.016 mmol) prepared in accordance with A.L. Casalnuovo et al. J. Am. Chem. Soc. 1990, 112, 4324-4330, triethylamine (0.02 mL, 0.1 mmol) and the alkyne (Compound 6b) (20 mg, 0.061 mmol) were added. Few crystals of CuI were added. The reaction mixture was stirred for 6 h. The triethylammonium salt of LH8037 was achieved after purification by RP-HPLC (eluent: 100mM triethylammonium acetate \rightarrow 20% acetonitrile in 100mM triethylammonium acetate). $^1\text{H-NMR}$ (D_2O): δ 8.1 (1H, CH), 6.2 (1H, CH), 4.8 (1H, CH), 4.6 (1H, CH), 4.1 (3H, CH, CH_2), 2.8 (2H, CH_2), 2.7 (2H, CH_2), 2.5 (2H, CH_2), 2.3 (2H, CH_2), 1.4 (18H, 6 x CH_3).

[0566] Immediately prior to incorporation or after incorporation, the protective di-*tert*-butyl ester groups may be cleaved to obtain the corresponding free carboxylic acid.

Examples 31 to 32: Preparation of the mononucleotide building block (VII)

Example 31: Preparation of 2-[5-[4-Amino-1-(4-hydroxy-5-hydroxymethyl-tetrahydrofuran-2-yl)-2-oxo-1,2-dihydro-pyrimidin-5-yl]-pent-4-ynoylamino]-succinic acid di-*tert*-butyl ester (7a)

[0567]

[0568] Compound (7a) (30 mg, 19%) was obtained from compound (6b) (140 mg, 0.43 mmol) and 5-iodo-2-deoxycytidine (100 mg, 0.28 mmol) using the procedure described for the synthesis of compound VI. ¹H-NMR (MeOD-D₃): δ 8.3 (1H, CH), 6.2 (1H, CH), 4.8 (1H, CH), 4.6 (1H, CH), 4.4 (1H, CH), 4.0 (1H, CH), 3.8 (2H, CH₂), 2.8 (4H, 2 x CH₂), 2.7 (2H, CH₂), 2.4 (1H, CH₂), 2.2 (1H, CH₂), 1.4 (18H, 6 x CH₃).

Example 32: Preparation of 2-[5-[4-Amino-1-(4-hydroxy-5-(O-triphosphate-hydroxymethyl)-tetrahydro-furan-2-yl)-2-oxo-1,2-dihydro-pyrimidin-5-yl]-pent-4-ynoylamino]-succinic acid di-tert-butyl ester (Compound VII)

[0569]

[0570] Phosphoroxyl chloride (6.0 μl, 0.059 mmol) was added to a cooled solution (0 °C) of 7a (30 mg, 0.054 mmol) in trimethyl phosphate (1 mL). The mixture was stirred for 1 h. A solution of bis-*n*-tributylammonium pyrophosphate (77 mg, 0.16 mmol) in DMF (1 mL) and tributylamine (40 μl, 0.16 mmol) were added. Water (2 mL) was added. pH of the solution was measured to be neutral. The solution was stirred at room temperature for 3 h and at 5 °C overnight. A small amount of compound VII (few mg) was obtained after purification by RP-HPLC (eluent: 100mM triethylammonium acetate → 20% acetonitrile in 100mM triethylammonium acetate). 7a (18 mg) was regained.

[0571] Immediately prior to or subsequent to incorporation the protective di-*tert*-butyl ester groups may be cleaved to obtain the corresponding free carboxylic acid.

Examples 33 and 34: Preparation of the mononucleotide building block (VIII)Example 33: Preparation of 2-Pent-4-ynoylamino-6-(2,2,2-trifluoroacetyl-amino)-hexanoic acid, (8a)**[0572]**

[0573] Compound 6a (250 mg, 1.0 mmol) was added to a solution of *N*-ε-trifluoroacetyl-L-lysine (Novabiochem, 04-12-5245) (250 mg, 1.0 mmol) in DMF (3 mL). Ethyldiisopropylamine (0.2 mL, 1.2 mmol) was added. The solution was stirred at room temperature overnight and worked-up by RP-HPLC (eluent: water → methanol). Yield: 50 mg, 15%. ¹H-NMR (D₂O): δ 4.4 (1H, CH), 3.4 (2H, CH₂), 2.5 (4H, 2 x CH₂), 2.3 (1 H, CH), 1.9 (1 H, CH₂), 1.8 (1H, CH₂) 1.6 (2H, CH₂), 1.5 (2H, CH₂).

Example 34: Preparation of 2-[5-[1-(4-Hydroxy-5-(*O*-triphosphate-hydroxymethyl)-tetrahydrofuran-2-yl)-2,4-dioxo-1,2,3,4-tetrahydro-pyrimidin-5-yl]-pent-4-ynoylamino]-6-(2,2,2-trifluoro-acetyl-amino)-hexanoic acid (Compound VIII)

[0574]

[0575] The triethylammonium salt of compound VIII (11 mg) was obtained from compound 8a (50 mg, 0.15 mmol) and 5-iodo-2-deoxyuracil (50 mg, 0.06 mmol) using the procedure described for the synthesis of compound VI.

Examples 35 to 39: Preparation of the mononucleotide building block (IX)Example 35: Preparation of di-Boc-Lysin-propargyl amide (compound 9a) C₁₉H₃₃N₃O₅ Mw 383.48**[0576]**

[0577] Boc-Lys-(Boc)-OSu (Novabiochem 04-12-0017, 0.887 g, 2 mmol) was dissolved in THF (10 ml). Propargylamine (0.412 ml, 6 mmol) was added and the solution stirred for 2 h. TLC (ethylacetate:heptan 1:1) showed only one product. Dichloromethane (20 ml) was added and the mixture was washed successively with citric acid (1M, 10 ml) and saturated sodium hydrogen carbonate (10 ml). The organic phase was dried with magnesium sulphate filtered and evaporated to give compound 9a (0.730 g) as a colourless syrup.

$^1\text{H-NMR}$: δ 6.55 (1H, NH), 5.15 (1H, NH), 4.6 (1H, $\underline{\text{CH-NH}}$), 4.05 (2H, $\text{CH-C-}\underline{\text{CH}_2\text{-N}}$), 3.75 (1H, NH), 3.1 (2H, $\underline{\text{CH}_2\text{-NH}}$) 2.25 (1H, CH-C-CH_2), 1.9-1.3 (6H, 3 x CH_2), 1.4 (18H, 6 x CH_3).

Example 36: Preparation of 5-Iodo-3'-O-acetyl-5'-O-TBDMS-2'-deoxyuridine (compound 9b)- $\text{C}_{17}\text{H}_{27}\text{I}\text{N}_2\text{O}_6\text{Si}$ Mw 510.40

[0578]

[0579] 5-Iodo-2'-deoxyuridine (Sigma I-7125, 2.50 g, 7.06 mmol) and imidazol (0.961 g, 14.12 mmol) was dissolved in DMF (10 ml). Cooled to 0 °C and a solution of TBDMSCl (t-butyl-dimethyl-chloride, 1.12 g, 7.41 mmol) in dichloromethane (5.0 ml) was run in over 20 minutes. Stirring was continued at room temperature for 18 h, and the mixture was evaporated. The crude mono silylated nucleoside was dissolved in pyridine (40 ml) and cooled to 0 °C. Acetic anhydride (4.0 ml, 42.3 mmol) was added over 30 minutes and stirring was continued for 18 h at room temperature. The reaction mixture was evaporated and dissolved in dichloromethane (20 ml) and citric acid (2M, 20 ml) was added. The aqueous phase was back extracted with dichloromethane (2 x 20 ml). The combined organic phases were washed with saturated sodium bicarbonate (20 ml), dried with sodium sulphate and evaporated (5.85 g). Recrystallisation from ethylacetate/EtOH gave 9b (2.54, g) pure for synthesis TLC (Ethyl acetate). Further recrystallisation furnished an analytical pure sample mp.172.4-173.1°C.

Example 37: Preparation of 5-Iodo-3'-O-acetyl-2'-deoxyuridine (compound 9c) $C_{11}H_{13}IN_2O_6$ Mw 396.14

[0580]

[0581] 5-Iodo-3'-O-acetyl-5'-O-TBDMS-2'-deoxyuridine (compound 9b) (2.54 g, 4.98 mmol) as dissolved in THF (25 ml), tetra butyl ammonium fluoride trihydrat (TBAF, 3.2 g, 10.1 mmol) was added and stirred for 18 h at room temperature. The reaction mixture was added water (25 ml) stirred for 1 h. Ion exchange resin IR-120 H^+ (26 ml) was then added and stirring was continued for 1 h. The solution was filtered and reduced to approximately 10 ml in vacuo. Crystals were collected and dried in vacuo (1.296g)

Example 38: Preparation of 5-Iodo-5'-triphosphate-2'-deoxyuridine triethylammonium salt (compound 9d) $C_{9}H_{14}IN_2O_{14}P_3 + n \cdot N(CH_2CH_3)_3$ Mw 897.61 for $n=3$.

[0582]

[0583] 5-Iodo-3'-O-acetyl-2'-deoxyuridine (compound 9c) (2.54 g, 4.98 mmol) as dissolved in pyridine (3.2 ml) and dioxane (10 ml). A solution of 2-chloro-4H-1,3,2-benzodioxaphosphorin-4-one in dioxane (3.60 ml, 1 M, 3.60 mmol) was added under stirring. The reaction mixture was stirred for 10 minutes at room temperature followed by simultaneous addition of bis(tri-n-butylammonium) pyrophosphate in DMF (9.81 ml, 0.5 M, 4.91 mmol) and tri-n-butylamine (3.12 ml, 13.1 mmol). Stirring was continued for 10 minutes and the intermediate was oxidized by adding an iodine solution (90 ml, 1% w/v in pyridine/water (98/2, v/v)) until permanent iodine colour. The reaction mixture was left for 15 minutes and then decolorized with sodium thiosulfate (5% aqueous solution, w/v). The reaction mixture was evaporated to yellow oil. The oil was stirred in water (20 ml) for 30 minutes and concentrated aqueous ammonia (100 ml, 25%) was added. This mixture was stirred for 1.5 hour at room temperature and then evaporated to an oil of the crude triphosphate product. The crude material was purified using a DEAE Sephadex A25 column (approximately 100 ml) eluted with a linear gradient of triethyl- ammonium hydrogencarbonate [TEAB] from 0.05 M to 1.0 M (pH approximately 7.0 - 7.5); flow 8 ml/fraction/ 15 minutes. The positive fractions were identified by RP18 HPLC eluting with a gradient from 10 mM TEAA (triethylammonium acetate) in water to 10 mM TEAA 20% water in acetonitrile. The appropriate fractions were pooled and evaporated. Yield approximately 1042 mg.

Example 39: Preparation of 5-(Lysin-propargyl amide)-5'-triphosphate-2'-deoxycytidine, triethylammonium salt (compound IX) $C_{18}H_{30}N_5O_{15}P_3 + n \cdot N(CH_2CH_3)_3$ Mw 952.95 for $n=3$

[0584]

[0585] 5-Iodo-3'-O-acetyl-5'-triphosphate-2'-deoxyuridine, triethylammonium salt (compound 9d) (0.0087 g, 9.7 μ mol) was dissolved in water (100 μ l). Air was replaced carefully with argon. Di-Boc-Lysin-propargyl amide (compound 9a) (18.6 mg, 48.5 μ mol) dissolved in dioxane (100 μ l), triethylamine (2.7 μ l, 19.4 μ mol), $Pd((PPh_2)(m-C_6H_4SO_3Na^+)(H_2O))_4$ (compound 9d) (5 mg, 4.4 μ mol) and copper (I) iodide (0.4 μ l, 2.1 μ mol) were added in the given order. The reaction mixture was stirred for 18 h at room temperature in an inert atmosphere then evaporated. The crude material was treated with aqueous hydrochloric acid (0.2 M, 1 ml) for 15 minutes at 30 $^{\circ}$ C. (compound IX) was obtained by HPLC C_{18} 10 mM TEAA (triethylammonium acetate) in water to 10 mM TEAA 20% water in acetonitrile. Appropriate fractions were desalted using gelfiltration (pharmacia G-10, 0.7 ml).

Examples 40 to 45: Preparation of the mononucleotide building block (X)

Example 40: Preparation of Boc-Lys-(Boc)-OH (compound 10a) $C_{16}H_{30}N_2O_6$ Mw 346.42

[0586] Lysine (Novabiochem 04-10-0024; 3.65 g, 20 mmol) was dissolved in sodium hydroxide (2 M, 40 ml), added dioxane (60 ml) and di-tert-butyl dicarbonate (8.73 g, 40 mmol) in the given order. The mixture was stirred for 1.75 h at 60 $^{\circ}$ C. Water (50 ml) was added and the solution was washed with dichloromethane (4 x 25 ml). The aqueous phase was cooled to 0 $^{\circ}$ C with ice then acidified with 2 M HCl (pH = 3) and extracted with dichloromethane (4 x 25 ml). The organic phase was dried with magnesium sulphate. Evaporation furnished (compound 10a) 6.8 g as a colour less oil. 1H -NMR: δ 9.5 (1H, COOH), 5.3 (1H, CH), 4.7 (1H, NH), 4.3 (1H, NH), 3.1 (2H, CH_2 -NH), 1.8 (2H, CH_2 -CH), 1.5 (6H, $3 \times CH_3$), 1.45 (18H, $6 \times CH_3$).

Example 41: Preparation of di-Boc-Lysin-propargyl ester (compound 10b) $C_{19}H_{32}N_2O_6$ Mw 384.47

[0587]

[0588] Boc-Lys-(Boc)-OH (compound 10a) (3.46 g, 10 mmol) was dissolved in THF (25 ml). At 0 °C a solution of dicyclohexylcarbodiimide (2.02 g, 10 mmol) in THF (25 ml) and triethylamine (1.39 ml) were added in the given order. The mixture was allowed to warm up to room temperature and stirred for 18 h. The resulting suspension was filtered and evaporated. The oil 5.45 g was pre-purified by column chromatography Heptan: Ethylacetate 3:1.

Pure 10b was achieved by HPLC- C₁₈ 10% MeOH: 90% H₂O → 100% MeOH

¹H-NMR: δ 5.1 (1H, NH), 4.75 (2H, CH-C-CH₂-O), 4.6 (1H, NH), 4.35 (1H, CH-NH), 3.1 (2H, CH₂-NH) 2.5 (1H, CH-C-CH₂), 1.9-1.4 (6H, 3 x CH₂), 1.5 (18H, 6 x CH₃).

Example 42: Preparation of 5-Iodo-3',5'-di-O-TBDMS-2'-deoxycytidine (compound 10c) C₂₁H₄₀N₃O₄Si₂ Mw 581.64

[0589]

[0590] 5-Iodo-2'-deoxy-Cytidine (Sigma I -7000, 0.353 g, 1 mmol) was dissolved in DMF (4 ml), added t-Butyl-dimethyl silyl chloride (TBDMS-Cl, 0.332 g, 2.2 mmol) and Imidazol (0.204 g, 3 mmol). The solution was stirred for 15 h at 50 °C followed by evaporation. Dichloromethane (25 ml) and citric acid (2M, 10 ml) was added to the dry mixture. The aqueous phase was back extracted with dichloromethane (2 x 10 ml). The combined organic phases were washed with saturated sodium bicarbonate (15 ml), dried with sodium sulphate and evaporated. Compound 10 c (0.405 g) was obtained by recrystallisation from EtOH/Ethylacetate.

¹H-NMR: δ 8.1 (1H, H-6), 6.25 (1H, H-1'), 4.35 (1H, H-4'), 4.0 (1H, H-4'), 3.9 (1H, H-5'), 3.75 (1H, H-5'), 2.5 (1H, H-2'), 1.95 (1H, H-2'), 1.85 (2H, NH), 0.95 (9H, 3 x CH₃), 0.9 (9H, 3 x CH₃), 0.15 (6H, 2 x CH₃), 0.1 (6H, 2 x CH₃).

Preparation of 5-(di-Boc-Lysin-propargyl ester)-3' 5'-di-O-TBDMS-2'-deoxycytidine (compound 10d) C₄₀H₇₁N₅O₁₀Si₂ Mw 838.19

[0591]

[0592] Compound 10c (0.116 g, 0.2 mmol) was dissolved in dichloromethane (10 ml). Air was replaced carefully with argon. Di-Boc-Lysin-propargyl ester (compound 10b) (0.232, 0.6 mmol), triethylamine (0.083 ml, 0.6 mmol), di-chloro-bis-triphenylphosphine-palladium II (0.0074 g, 0.01 mmol) and copper (I) iodide (0.0038 g, 0.02 mmol) were added in

the given order. The reaction mixture was stirred for 15 h at room temperature in an inert atmosphere. The reaction mixture was evaporated re-dissolved in MeOH/H₂O 1:1 1 ml and purified using HPLC-C₁₈ 45% H₂O:55% MeCN → 100% MeCN.

¹H-NMR: δ 8.2 (1H, H-6), 6.25 (1H, H-1'), 5.15 (1H, NH), 4.9 (2H, C-CH₂-O), 4.6 (1H, NH), 4.4 (1H, H-4'), 4.3 (1H, CH-NH), 4.0 (1H, H-4'), 3.9 (1H, H-5'), 3.75 (1H, H-5'), 2.5 (1H, H-2'), 3.1 (2H, CH₂-NH), 1.95 (1H, H-2'), 1.9-1.4 (6H, 3 x CH₂), 1.85 (2H, NH), 1.5 (18H, 6 x CH₃), 0.95 (9H, 3 x CH₃), 0.9 (9H, 3 x CH₃), 0.15 (6H, 2 x CH₃), 0.1 (6H, 2 x CH₃).

Example 44: Preparation of 5-(di-Boc-Lysin-propargyl ester)-2'-deoxycytidine (compound 10e) C₂₈H₄₃N₅O₁₀ Mw 609.67

[0593]

[0594] Compound 10d (0.0246 g, 0.029 mmol) was dissolved in THF (1 ml) and successively added acetic acid (0.0165 ml, 0.288 mmol) and tetra n-butyl ammonium fluoride tri-hydrate (0.0454 g, 0.144 mmol). The reaction mixture was stirred for 18 h at room temperature and afterwards evaporated. Re-dissolved in dichloromethane and purified on silica (1 x 18 cm). Dichloromethane/MeOH 8:2. Fractions which gave UV absorbance on TLC were pooled and evaporated giving (0.0128 g) as a colourless oil.

Example 45: Preparation of 5-(Lysin-propargyl ester)-5'-triphosphate-2'-deoxycytidine C₁₈H₃₀N₅O₁₅P₃ Mw 649.38

[0595]

[0596] Compound 10e (0.0128 g, 0.021 mmol) was dissolved in trimethylphosphate (0.150 ml) and cooled to 0 °C. Phosphoroylchloride in trimethylphosphate (1M, 0.0246 ml) was added slowly in order not to raise the temperature. Stirring was continued for 2 h at 0 °C and the temperature was allowed to rise to ambient. Pyrophosphate in DMF (0.5 M, 0.1025 ml, 0.051 mmol) and tri-n-butyl amine in DMF (1M, 0.0122 ml, 0.051 mmol) were added simultaneously. Stirring was continued for 15 minutes at room temperature and TEAB(triethyl ammonium bicarbonate, 1M, pH = 7.3, 0.50ml) was added. Stirring was continued for 3 h then evaporated.

Example 46: Preparation of compound X

[0597]

[0598] The crude material was treated with aqueous hydrochloric acid (0.2 M, 1 ml) for 15 minutes at 30 °C. Compound X was obtained by HPLC C₁₈ 10 mM TEAA (triethylammonium acetate) in water to 10 mM TEAA 20% water in acetonitrile. Appropriate fractions were desalted using gelfiltration (pharmacia G-10, 0.7 ml)

Examples 47 to 51: Preparation of the mononucleotide building block (XI)

Example 47: Preparation of 3'-O-acetyl-5'-O-dimethoxytrityl-5-iodo-2'-deoxyuridine (compound 11a). C₃₂H₃₁IN₂O₈. Mw 698.51 g/mol. (Analogous to "Oligonucleotide Synthesis - a practical approach" (1984) Gait, M.J. (Ed.), IRL Press, Oxford.)

[0599]

[0600] 5-Iodo-2'-deoxyuridine (3.54 g, 10 mmol) was dried by coevaporation with pyridine (25 ml, 3 times). Pyridine (100 ml) was added and shortly evaporated to a reduced volume (80 ml). 4,4'-dimethoxytrityl chloride (DMT-Cl, 3.38 g, 10 mmol) was added and the reaction mixture was stirred at room temperature. After 20 hours, additional DMT-Cl (0.68 g, 2 mmol) was added and the reaction mixture was stirred for another 4 hour. Excess of DHT-Cl was quenched with methanol (5 ml, stirred 10 minutes) and the reaction mixture evaporated to dryness. The oil was dissolved in dichloromethane (100 ml) and extracted with saturated aqueous NaHCO₃ (100 ml). The aqueous phase was back-extracted with dichloromethane and the combined fractions of dichloromethane were dried with anhydrous MgSO₄, filtered and evaporated. The crude oil was dissolved in dichloromethane (75 ml) and triturated with pentane (250 ml). Re-trituration of the crude oil by dissolving in ethyl acetate (75 ml) and adding pentane (250 ml) gave reddish foam after evaporation. Yield of crude 5'-O-dimethoxytrityl-5-iodo-2'-deoxyuridine was 5.84 g. Pure S'-O-dimethoxytrityl-S-iodo-2'-deoxyuridine was obtained via column chromatography in dichloromethane on silica (Merck Kieselgel 60, 230-400 mesh ASTM, art.

9385) eluting with a gradient of methanol (0-5 % methanol in dichloromethane). Yield of purified 5'-O-dimethoxytrityl-5-iodo-2'-deoxyuridine was 4.26 g (6.5 mmol, 65%). 5'-O-Dimethoxytrityl-5-iodo-2'-deoxyuridine (6.0 g, 9.1 mmol) was dried by coevaporation with pyridine (10 ml, twice). Pyridine (50 ml) was added and acetic anhydride (5 ml) and dimethylaminopyridine (DMAP, catalytic amount) were added. The reaction mixture was stirred overnight at room temperature. Excess of acetic anhydride was quenched with methanol (10 ml, stirred 15 min.) and the reaction mixture evaporated to dryness. The oil was dissolved in dichloromethane (150 ml) and extracted with aqueous saturated NaHCO_3 (50 ml). The aqueous phase was back-extracted with dichloromethane and the combined fractions of dichloromethane were dried with anhydrous MgSO_4 filtered and evaporated. Purified 3'-O-acetyl-5'-O-dimethoxytrityl-5-iodo-2'-deoxyuridine was obtained via column chromatography in dichloromethane/methanol (98/2, v/v) on silica (Merck Kieselgel 60, 230-400 mesh ASTM, art. 9385) eluting with a gradient of methanol (2-6 % methanol in dichloromethane). The yield was 5.75 g (8.2 mmol). Rechromatography in dichloromethane/pentane (80/20, v/v) eluting with a gradient of methanol (2-6%) gave the desired purified 3'-O-acetyl-5'-O-dimethoxytrityl-5-iodo-2'-deoxyuridine (4.18 g, 6.0 mmol, 60%).

Example 48: Preparation of N-trifluoroacetyl-3-amidopropyne (compound 11b). $\text{C}_5\text{H}_4\text{F}_3\text{NO}$. Mw. 151.09 g/mol. (Reference: Cruickshank et al. (1988) *Tetrahedron Lett.* 29 5221-5224).

[0601]

[0602] Propargylamine (7.0 ml, 5.88 g, 0.11 mol) was dissolved in 100 ml ice-cold methanol and ethyl trifluoroacetate (18 ml, 19.2 g, 0.135 mol) was added slowly under stirring on ice. The ice bath was removed and the reaction mixture was allowed to warm up to room temperature and stirring was continued over night. After 24 h, TLC analysis (Silica, dichloromethane/methanol, 9/1, v/v) showed complete conversion of propargylamine (as observed by disappearance of the positive colour-reaction in the ninhydrin test, 110 °C). The reaction mixture was evaporated, re-dissolved in dichloromethane (100 ml) and extracted with aqueous sodium hydrogen carbonate. The aqueous phase was back-extracted with dichloromethane (25 ml) and the combined dichloromethane phases were extracted with water (100 ml). The aqueous phase was back-extracted with dichloromethane (25 ml) and the combined dichloromethane phases were dried with magnesium sulfate, filtered and evaporated to yellow oil. The oil was purified by distillation collecting the purified product at 38-39 °C/1 mmHg. Yield 11.0 g (73 mmol, 66%).

Example 49: Preparation of 3'-O-acetyl-5'-O-dimethoxytrityl-5-(N-trifluoroacetyl-3-amido-propynyl)-2'-deoxyuridine (compound 11c). $\text{C}_{35}\text{H}_{35}\text{N}_3\text{O}_8$, Mw 625.67 g/mol.

[0603]

[0604] 3'-O-Acetyl-5'-O-dimethoxytrityl-5-iodo-2'-deoxyuridine (4.15 g, 6.0 mmol) was dissolved in ethyl acetate (240 ml) and N-trifluoroacetyl-3-aminopropyne (1.81 g, 12 mmol), triethylamine (3.09 g, 4.23 ml, 30.5 mmol), bis(triphenylphosphine)-palladium(II) chloride (0.091 g, 0.13 mmol) and copper(I) iodide (0.091 g, 0.48 mmol) were added in the given order. The reaction mixture was flushed with nitrogen, stoppered and stirred at ambient temperature. The reaction was followed by TLC analysis (Silica, CH₂Cl₂/MeOH, 95/5, v/v) and stopped after 24 hours when all starting material was consumed. The reaction mixture was extracted twice with aqueous EDTA (5% v/v, 300 ml) and once with aqueous sodium thiosulfate (5% v/v, 300 ml). The aqueous phases were back-extracted with ethyl acetate and the combined fractions of ethyl acetate were dried (anhydrous MgSO₄), filtered and evaporated. Column chromatography in dichloromethane/pentane (80/20, v/v) eluting with a gradient of methanol (0-5%) gave the crude 3'-O-acetyl-5'-O-dimethoxytrityl-5-(N-trifluoroacetyl-3-amidopropynyl)-2'-deoxyuridine (4.2 g) as brownish oil. Rechromatography in ethylacetate/pentane (50/50 to 60/40, v/v) gave the desired purified product (1.99 g, 3.2 mmol).

Example 50: Preparation of 3'-O-acetyl-5-(N-trifluoroacetyl-3-amidopropynyl)-2'-deoxyuridine. C₁₆H₁₆F₃N₃O₇, Mw 419.31 g/mol.

[0605]

[0606] 3'-O-Acetyl-5'-O-dimethoxytrityl-5-(N-trifluoroacetyl-3-amidopropynyl)-2'-deoxyuridine (1.99 g, 2.8 mmol) was dissolved in dichloromethane (133 ml) and cooled to 0 °C. A solution of trichloroacetic acid in dichloromethane (3% w/v) was added slowly and the reaction mixture was stirred for 15 min at 0 °C. TLC analysis (Silica, CH₂Cl₂/MeOH, 95/5 v/v) confirmed total detritylation and the reaction was quenched by the addition of 2-propanol (10 ml), quenching of DMT⁺ was observed by colour-change from orange to colourless. Stirring was continued for 2 minutes and the reaction mixture

was poured into saturated aqueous NaHCO_3 (100 ml) and extracted twice with dichloromethane. The aqueous phase was back-extracted with dichloromethane and the combined fractions of dichloromethane were dried (anhydrous MgSO_4), filtered and evaporated. The foam was dissolved in dichloromethane (50 ml) and triturated with pentane (200 ml). The trituration was repeated and the precipitate was redissolved and evaporated, first from methanol and then from chloroform to give yellow foam. Purified 3'-O-acetyl-5-(N-trifluoroacetyl-3-amidopropynyl)-2'-deoxyuridine was obtained by silica gel column chromatography in dichloromethane/methanol (gradient: 95/5 to 89/11, v/v), The yield was. 0.37 g after rechromatography, eluting with a gradient in dichloromethane/methanol (98/2 to 95/5, v/v).

Example 51: Preparation of 5-(3-aminopropyl)-5'-triphosphate-2'-deoxyuridine, triethylammonium salt (compound XI).
 $\text{C}_{12}\text{H}_{18}\text{N}_3\text{O}_{14}\text{P}_3 + n\text{-N}(\text{CH}_2\text{CH}_3)_3$; Mw 824.78 g/mol for $n = 3$. (Ludwig, J. and Eckstein, F. (1989) J. Org. Chem. 54, 631-635).

[0607]

[0608] 3'-O-Acetyl-5-(N-trifluoroacetyl-3-amidopropynyl)-2'-deoxyuridine (42.5 mg, 0.10 mmol) was dissolved in anhydrous pyridine (2 ml) and evaporated. The oil was dissolved in anhydrous pyridine (100 μl) and anhydrous dioxane (300 μl). A solution of 2-chloro-4H-1,3,2-benzodioxaphosphorin-4-one in dioxane (110 μl , 1 M, 0.11 mmol) was added under stirring and after 30 seconds precipitation of pyridinium hydrochloride was observed. The reaction mixture was stirred for 10 minutes at room temperature followed by simultaneous addition of bis(tri-n-butylammonium) pyrophosphate in DMF (300 μl , 0.5 M) and tri-n-butylamine (100 μl). Stirring was continued for 10 minutes and the intermediate was oxidized by adding an iodine solution (3 ml, 1% w/v in pyridine/water (98/2, v/v)) until permanent iodine colour. The reaction mixture was left for 15 minutes and then decolourized with sodium thiosulfate (4 drops, 5% aqueous solution, w/v). The reaction mixture was transferred to a roundbottom flask (50 ml) with water and evaporated to yellow oil. The oil was stirred in water (10 ml) for 30 minutes and concentrated aqueous ammonia (20 ml, 32%) was added. This mixture was stirred for 1 hour at room temperature and then evaporated to an oil of the crude triphosphate product. The crude material was purified using a DEAE Sephadex A25 column (approximately 100 ml) eluted with a linear gradient of triethylammonium hydrogencarbonate [TEAB] from 0.05 M to 1.0 M (pH approximately 7.5 - 8.0); flow 8 ml/fraction/15 minutes. The positive fractions were identified by RP18 HPLC eluting with a gradient from 10 mM TEAA (triethylammonium acetate) in water to 10 mM TEAA 20% water in acetonitrile. The appropriate fractions were pooled and evaporated. Yield approximately 90 mg.

Examples 52 to 54: Preparation of the mononucleotide building block (XII)

Example 52: Succinic acid mono-(3-tert-butoxycarbonylamino-propyl) ester (Compound 12a)

[0609]

12a

[0610] Triethylamine (5.0 mL, 36 mmol) and di-*tert*-butyl dicarbonate (7.0 g, 32 mmol) were added to a solution of 3-aminopropanol (1.0 g, 26.6 mmol) in methanol (10 mL). The solution was stirred for 2 h. at room temperature. Methanol was evaporated off and the residue was dissolved in water (50 mL) and extracted with dichloromethane (50 mL). The organic phase was dried (Na_2SO_4) and concentrated *in vacuo*. The crude material was dissolved in dichloromethane (20 mL) and DMF (4 mL). Triethylamine (5.0 mL, 36 mmol) and succinic anhydride (3.0 g, 30 mmol) were added portion wise to the solution (exothermic reaction). The reaction mixture was stirred for 2 h, then concentrated and worked-up by RP-HPLC (eluent: water \rightarrow methanol). Yield 6.0 g, 82%. $^1\text{H-NMR}$ (CDCl_3): δ 4.2 (2H, CH_2), 3.2 (2H, CH_2), 2.7 (4H, 2 x CH_2), 1.8 (2H, CH_2), 1.4 (9H, 3 x CH_3).

9-[4-(Isopropyl-dimethyl-silanyloxy)-5-(isopropyl-dimethyl-silanyloxymethyl)-tetrahydro-furan-2-yl]-9H-purin-6-ylamine (compound 12b)

[0611]

12b

[0612] Imidazole (2.0 g, 29.4 mmol) and *tert*-butyldimethylsilyl chloride (3.0 g, 19.9 mmol) were added to a solution of deoxyadenosine monohydrate (1.33, 4.94 mmol) in DMF (10 mL). The solution was stirred at 60°C overnight. The mixture was concentrated to a solid *in vacuo*. Work-up by flash chromatography afforded crystalline compound 12b in a yield of 2.1 g, 94%. $^1\text{H-NMR}$ (CDCl_3): δ 8.3 (1H, HC=), 8.1 (1H, HC=), 6.4 (1H, CH), 6.0 (2H, 2 x OH), 4.6 (1H, CH), 4.1 (1H, CH), 3.9 (1H, CH), 3.8 (1H, CH), 2.6 (1H, CH_2), 2.4 (1H, CH_2), 0.9 (18H, 6 x CH_3), 0.0 (12H, 4 x CH_3).

Example 53: N-[9-(4-Hydroxy-5-hydroxymethyl-tetrahydrofuran-2-yl)-9H-purin-6-yl]-succinamic acid 3-*tert*-butoxycarbonylamino-propyl ester (compound 12d)

[0613]

[0614] A solution of dicyclohexylcarbodiimide (366 mg, 1.78 mmol) in ethyl acetate (15 mL) was added to an ice-water cooled solution of 12a (488 mg, 1.78 mmol) in THF (10 mL). Few crystals of 4-dimethylaminopyridine and 12b (850 mg, 1.78 mmol) were added. The reaction temperature was slowly raised to room temperature and the mixture was stirred overnight. Precipitated salts were filtered off. The organic phase was washed with saturated NaHCO_3 (20 mL), dried (Na_2SO_4) and concentrated to a solid. Approximately 20 mg of 12c was isolated after flash chromatography and 510 mg of starting material 12b was regained. 12c (20 mg) was dissolved in THF (2 mL). Tetrabutylammonium fluoride, trihydrate (100 mg) and acetic acid (0.2 mL) were added. The mixture was stirred for 1 day, then concentrated *in vacuo* and worked-up by column chromatography. Yield 10 mg. Compound 12c $^1\text{H-NMR}$ (CDCl_3): δ 8.4 (1H, HC=), 8.2 (1H, HC=), 6.4 (1H, CH), 5.8 (2H, 2 x OH), 4.6 (1H, CH), 4.2 (2H, CH_2), 4.1 (1H, CH), 3.8 (1H, CH), 3.7 (2H, CH_2), 3.0 (4H, 2 x CH_2), 2.7 (3H, 2 x CH_2), 2.4 (1 H, CH_2), 1.8 (2H, CH_2), 1.4 (9H, 3 x CH_3), 0.9 (18H, 6 x CH_3), 0.0 (12H, 4 x CH_3). Selected NMR data for 12d: $^1\text{H-NMR}$ (MeOD-D_3): δ 4.6 (1H, CH), 4.1 (2H, CH_2), 3.8 (1H, CH), 3.7 (1H, CH), 3.6 (2H, CH_2), 3.2 (2H, CH_2), 3.0 (2H, CH_2), 2.8 (3H, 2 x CH_2), 2.5 (1 H, CH_2), 1.8 (2H, CH_2), 1.4 (9H, 3 x CH_3).

Example 54: *N*-[9-(4-Hydroxy-5-hydroxymethyl-tetrahydrofuran-2-yl)-9H-purin-6-yl]-succinamic acid 3-*tert*-butoxycarbonylamino-propyl ester (compound XII)

[0615]

[0616] LH8075b (10 mg) was converted to the corresponding triphosphate LH8075c using the procedure described

for the synthesis of compound VII. TLC indicated full conversion of compound 12d.

[0617] Immediately prior to incorporation, the tert-butoxy group may be hydrolysed to release the free carboxylic acid. Alternatively, the tert-butoxy group may be cleaved after the formation of the templated molecule.

Example 55: N-[9-(4-Hydroxy-5-(O-triphosphate-hydroxymethyl)-tetrahydrofuran-2-yl)-9H-purin-6-yl]-succinamic acid (Compound XIII)

[0618]

XIII

[0619] dATP (5 μ mol) was suspended in DMF (4×1 mL) and concentrated to a solid *in vacuo* four times. The solid was suspended in DMF (1 mL). Succinic anhydride (5 mg, 0.05 mmol) was added at -20°C . The mixture was stirred for 3h, and then concentrated to solid and purified by RP-HPLC (eluent: 0.1 % HCOOH in water \rightarrow 10% methanol, 0.1% HCOOH in water). The purified material was dissolved in aqueous ammonia (25%, 1 mL) and stirred for 3h. The mixture was concentrated *in vacuo* and worked-up by RP-HPLC (eluent: 0.1 % HCOOH in water \rightarrow 10% methanol, 0.1% HCOOH in water). Comparison with starting material indicated that the product eluted 40s later off the column than the starting material.

Examples 56 and 57: Preparation of the mononucleotide building block (XIV)

Example 56: Benzyloxy-ethynyl-diisopropyl-silane (Compound 14a)

[0620]

14a

[0621] A solution of benzyl alcohol (0.1 mL, 1.0 mmol) in THF (0.5 mL) was added dropwise to a cooled (-78°C) solution of diisopropylethylamine (1 mL), dichlorodiisopropylsilane (0.3 mL, 1.62 mmol) in THF (4 mL). The solution was stirred for 3h ($-78 \rightarrow -20^{\circ}\text{C}$). The mixture was cooled down to -78°C and lithiumacetylid-ethylenediamine-complex (250 mg, 2.71 mmol) was added. The reaction mixture was stirred for 5h ($-78 \rightarrow 20^{\circ}\text{C}$). Water (4 mL) was added. The mixture was extracted with dichloromethane (20 mL). The organic phase was dried (Na_2SO_4) and concentrated. Compound 14a (100 mg, 41%) was obtained after flash chromatography. $^1\text{H-NMR}$ (CDCl_3): δ 7.4 (5H, 5 x HC=), 5.0 (2H, CH_2), 2.6 (1H, CH), 1.0 (14H, 2 x CH, 2 x CH_3).

Example 57: 5-[[Diisopropyl-(2-methylene-pent-3-enyloxy)-silanyl]-ethynyl]-1-(4-hydroxy-5-(*O*-triphosphatehydroxymethyl)-tetrahydrofuran-2-yl)-1H-pyrimidine-2,4-dione (compound XIV)

[0622]

[0623] 5-Iodo-dUTP (200 mg, 0.56 mmol), diisopropylethylamine (0.1 mL) and 14a (100 mg, 0.41 mmol) were dissolved in DMF (2 mL). Argon was bubbled through the solution for 5 min. Tetrakis(palladium) (57 mg, 0.49 mmol) and CuI (19 mg, 0.1 mmol) were added and the mixture was stirred at 50°C for 5h. Solvent was evaporated off and 14b was purified by flash-chromatography. A NMR spectrum revealed the syrup consisted of 66%. The syrup (40 mg) was converted to the corresponding triphosphate (Compound XIV) using the procedure described for the synthesis of compound VII. TLC indicated full conversion of 14b. Selected NMR data for LH8061a: ¹H-NMR (MeOD-D₃): 6: 8.3 (1H, HC=), 7.3 (5H, HC=), 6.2 (1H, CH), 5.0 (2H, CH₂), 4.3 (1H, CH), 3.8-3.2 (3H, CH₂, CH), 2.3 (1H, CH₂), 2.2 (1H, CH₂), 1.0 (14H, 2 x CH, 4 x CH₃).

Examples 58 to 63: Preparation of the mononucleotide building block (XV)

[0624] Building block XV may be prepared according to the general scheme shown below:

Example 58: Preparation of compound 15a

[0625]

COMPOUND 15a

[0626] To a solution of 3-amino-butyric acid (2.06 g, 20 mmol) in NaHCO_3 (50% sat. aq, 25 mL) were added di-*tert*-butyl dicarbonate (4.36 g, 20 mmol) and acetonitrile (30 mL). The reaction mixture was stirred at room temperature for 18 h. Di-*tert*-butyl dicarbonate (4.36 g, 20 mmol) was added and the reaction mixture was stirred at room temperature for 18 h.

EtOAc (100 mL) was added and pH was adjusted to 4-5 by addition of NaH_2PO_4 . The product was extracted into EtOAc (3 x 100 mL), dried (Na_2SO_4), and evaporated to dryness under vacuum to afford crude product 4.6 g (113%).

Example 59: Preparation of compound 15b

[0627]

COMPOUND 15b

[0628] Compound 28 (1.023 g, 5.0 mmol), 3-Ethynyl-phenole (Lancaster, 0.675 g, 12 mmol) and 4-dimethylamino-pyridin (DMAP, 300 mg, 2.5 mmol) were dissolved in EtOAc (10 mL). Dicyclohexyl-carbodiimide (DCC, 2.06 g, 10 mmol) was added to the solution and after 16 h of stirring at room temperature, the reaction mixture was filtered and evaporated to dryness under vacuum. The crude product was purified by silica column chromatography eluting with EtOAc:Heptane gradient (1:3)-(1:2)(v/v). Product yield 720 mg, 73%.

^1H NMR (CDCl_3) δ 7.36-7.09 (4H, m, Ph), 4.89 (1 H, bs, NH), 4.22 (1H, bm, CH), 3.10 (1 H, s), 2.77 (2H, d), 1.40 (3H, t), 1.32 (3H, d).

Example 60: Preparation of compound 15c

[0629]

COMPOUND 15c

[0630] A solution of 5-Iodo-2'-deoxyuridine 3',5'-Di-*tert*-butyldimethylsilyl ether (730 mg, 1.25 mmol), triethylamine (250 mg, 2.5 mmol) and compound (15b) (456 mg, 1.5 mmol) in anhydrous DMF (3 mL) was stirred at room temperature. N₂ was passed through the solution for 20 min.

Tetrakis(triphenylphosphine)palladium(0) (109 mg, 0.094 mmol) and copper(I) iodide (36 mg, 0.188 mmol) were added and the reaction mixture was stirred at room temperature for 3 d.

The reaction mixture was evaporated and purified by silica column chromatography eluting with EtOAc:Heptane gradient (1:3)-(1:2)(v/v). Product yield 807 mg, 85%.

¹H NMR (CDCl₃) δ 8.38 (1 H, s), 8.08 (1 H, s, 6-H), 7.39-7.1 (4H, m, Ph), 6.33 (1 H, dd, 1'-H), 4.9 (1H, bs), 4.45 (1 H, dt), 4.80 (2H, s, CH₂), 4.2 (1 H, m), 4.02 (1 H, m, 4'-H), 3.95 (1H, dd, 5'-H), 3.79 (1H, dd, 5''-H), 2.78 (2H, d), 2.36 (1H, m, 2'-H), 2.07 (1 H, m, 2''-H), 1.46 (9H, s, ^tBu), 0.93 (9H, s, ^tBu), 0.91 (9H, s, ^tBu), 0.15 (3H, s, CH₃), 0.13 (3H, s, CH₃), 0.11 (3H, s, CH₃), 0.09 (3H, s, CH₃).

Example 61: Preparation of compound 15d

[0631]

COMPOUND 15d

[0632] A solution of compound (15c) (807 mg, 1.06 mmol), glacial acetic acid (1.0 g, 16 mmol) and tetrabutylammonium fluoride trihydrate (TBAF) (2.36 g, 7.5 mmol) in 20 mL dry THF was stirred at room temperature for 3 d.

The reaction mixture was evaporated and purified by silica column chromatography eluting with (DCM):(MeOH) (9:1) (v/v). Product yield 408 mg, 72%.

¹H NMR (CD₃OD) δ 8.46 (1H, s, 6-H), 7.39 (2H, m, Ph), 7.28 (1H, m, Ph), 7.12 (1H, m, Ph), 6.75 (1H, bd), 6.27 (1 H, dd, 1'-H), 4.44 (1 H, dt, 4'-H), 3.96 (1H, t, 3'-H), 3.86 (1H, dd, 5'-H), 3.77 (1H, dd, 5''-H), 2.72 (2H, d), 2.35-2.27 (2H, m, 2', 2''-H), 1.46 (9H, s, ^tBu), 1.27 (3H, d).

Example 62: Preparation of compound 15e

[0633]

COMPOUND 15e

[0634] Compound (15d) (138.5 mg, 260 μmol) was dissolved in 500 μL dry trimethylphosphate. After cooling to 0 °C, a solution of phosphorus oxychloride (POCl₃) in dry trimethylphosphate was added (400 μL stock solution (120 mg/mL), 310 μmol). The reaction mixture was stirred at 0 °C for 2h.

Subsequently a solution of tributylammoniumpyrophosphate (200 mg, 420 μmol in 1.00 mL dry DMF) and tributylamine (123 mg, 670 μmol in 500 μL dry DMF) was added at 0 °C. The reaction was stirred at room temperature for 3 min. and then stopped by addition of 1 mL 1.0 M triethylammoniumhydrogencarbonate.

Example 63: Preparation of compound XV

[0635]

COMPOUND XV

Removal of *N*-Boc protection group.

[0636] Following phosphorylation, 50 μL of the phosphorylation reaction mixture is adjusted to pH = 1 using HCl and incubated at room temperature for 30 minutes. The mixture is adjusted to pH 5.5 using equimolar NaOH and Na-acetate (pH 5.5) before purification on TLC.

Purification of nucleotide derivatives using thin-layer chromatography (TLC)

[0637] From the crude mixture, 20 samples of 2 μL were spotted on kieselgel 60 F₂₅₄ TLC (Merck). Organic solvents and non-phosphorylated nucleosides were separated from the nucleotides derivatives using 100% methanol as running solution. Subsequently, the TLC plate is air-dried and the nucleotide-derivative identified by UV-shadowing. Kiesel containing the nucleotide-derivative was isolated and extracted twice using 10 mM Na-acetate (pH = 5.5) as solvent. Kieselgel was removed by centrifugation and the supernatant was dried *in vacuo*. The nucleotide derivative was resuspended in 50-100 μL H₂O to a final concentration of 1-3 mM. The concentration of each nucleotide derivative was evaluated by UV-absorption prior to use in polymerase extension reactions.

Example 64: Polymerase incorporation of different nucleotide derivatives.

[0638] Different extension primers were 5'-labeled with ³²P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). These extension primers was annealed to a template primer using 0.1 and 3 pmol respectively in an extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl₂, pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooling to about 20 °C. The wild type nucleotide or nucleotide derivatives was then added (about 100 μM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. The samples were mixed with formamide dye and run on a 10% urea polyacrylamide gel electrophoresis. The gel was developed using autoradiography (Kodak, BioMax film). The incorporation can be identified by the different mobility shift for the nucleotide derivatives compared to the wild type nucleotide. Figure 49 shows incorporation of various nucleotide derivatives. In lane 1-5 the extension primer 5'-GCT ACT GGC ATC GGT-3' was used together with the template primer 5'-GCT GTC TGC AAG TGA TAA CCG ATG CCA GTA GC-3', in lane 6-11 extension primer 5'-GCT ACT GGC ATC GGT-3' was used together with the template primer 5'-GCT GTC TGC AAG TGA TGA CCG ATG CCA GTA GC-3', and in lane 12-15 the extension primer 5'-GCT ACT GGC ATC GGT-3' was used together with the template primer 5'-GCT GTC TGC AAG TGA CGT AAC CGA TGC CAG TAG C-3'. Lane 1, dATP; lane 2, Compound XI; lane 3, Compound IX; lane 4, Compound I; lane 5, Compound II; lane 6, no nucleotide; lane 7, dCTP; lane 8, Compound VII; lane 9, Compound X; lane 10, Compound IV; lane 11, Compound III; lane 12, no nucleotide; lane 13, dTTP; lane 14, dTTP and dATP; lane 15, dTTP and Compound X. These results illustrate the possibility to incorporate a variety of nucleotide derivatives of dATP, dTTP and dCTP using different linkers and functional entities. Other polymerases such as Taq, M-MLV and HIV have also been tested with positive results.

Example 65: Polymerase incorporation and hydrolysis of nucleotide derivatives containing cleavable ester linkers.

[0639] An extension primer (5'-GCT ACT GGC ATC GGT-3') was 5'-labeled with ³²P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). This extension primer was annealed with a template primer (5'-TAA GAC CGA TGC CAG TAG C-3') using 0.1 and 3 pmol respectively in an extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl₂, pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooling to about 20 °C. The wild type nucleotide or nucleotide derivatives was then added (about 100 μM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. Hydrolysed samples was treated with 0.1 M NaOH at 50 °C for about 15 min. and then titrated with equimolar HCl and NaOAc (pH 6.5) and purified by micro-spin gel filtration (BioRad). The samples were mixed with formamide dye and run on a 10% urea polyacrylamide gel electrophoresis. The gel was developed using autoradiography (Kodak, BioMax film). The incorporation can be identified by the different mobility shift for the nucleotide derivatives compared to the wild type nucleotide. Figure 50 shows the incorporation of various nucleotide derivatives. Lane 1, compound III and compound II; lane 2, compound III and two compound II; lane 3, hydrolysis of compound III and compound II; lane 4, hydrolysis of compound III and two compound II. The results show that these nucleotide derivatives can be incorporated by the polymerase in this specific order. It also shows that one or both the incorporated compound II nucleotide derivatives with an ester linker can specifically be hydrolysed on the DNA template and the incorporated compound III nucleotide derivative with no ester linker is intact. This illustrates the possibility to incorporate different nucleotide derivatives where one nucleotide derivative can function as the attachment point (non-cleavable linker) and at the same time liberate (cleavable linker) other incorporated nucleotide derivatives from the DNA template to create a displaying molecule. In addition, this experimental data shows that nucleotide derivatives with linkers containing cleavable ester can be inserted by the polymerase without reaction with amines in the active site of the polymerase or become hydrolysed during the incorporation process.

Example 66: Polymerase incorporation and cross-linking of nucleotide derivatives.

[0640] An extension primer (5'-GCT ACT GGC ATC GGT-3') was 5'-labeled with ³²P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). This extension primer was annealed with a template primer (5'-TAG ACC GAT GCC AGT AGC) using 0.1 and 3 pmol respectively in the extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl₂, pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooled to about 20 °C. The nucleotide derivatives was then added (about 100 μM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. The oligonucleotides were then purified using micro-spin gel filtration (BioRad). Cross-linking was performed using 10 mM BS₃ [Bis(sulfonylsuccinimide)suberate] (Pierce, cat# 21580) for about 1 hour at 30 °C. The samples were mixed with formamide dye and run on a 10% urea polyacrylamide gel electrophoresis. The gel was developed using autoradiography (Kodak, BioMax film). Figure 51A and 51B shows the incorporation and cross-linking (CL) of various nucleotide derivatives. Figure 51A: Lane 1, compound III and compound II; lane 2, cross-linked compound III and compound II. Figure 51B: Lane 1, compound III and compound I; lane 2, cross-linked compound III and compound I. The results show that these nucleotide derivatives can be incorporated by the polymerase in this specific order. It also shows that compound III, compound II and compound I is modified by the cross-linking reagent BS₃ (mobility shift) and thereby permit cross-linking (CL) between reactive groups on the nucleotide derivatives compound III-compound II and compound III-compound I mediated by the DNA template. Importantly, the amide groups of the nucleotide derivatives in the major groove are selectively accessible for modifications which promote cross-linking between different incorporated nucleotide derivatives on the DNA template.

Example 67: Polymerase incorporation of various nucleotide derivatives.

[0641] An extension primer (5'-TCC GCT ACT GGC ATC GGT-3') was 5'-labeled with ³²P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). This extension primer was annealed with a template primer (5'-TGA ACC GAT GCC AGT AGC-5') using 0.1 and 3 pmol respectively in the extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl₂, pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooled to about 20 °C. This template primer was 3'Biotin-C6-labeled to prevent extension. The nucleotide derivatives was then added (about 100 μM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. The samples were mixed with formamide dye and run on a 10% urea polyacrylamide gel electrophoresis. The gel was developed using autoradiography (Kodak, BioMax film). Figure 52 shows the incorporation of various nucleotide derivatives. Lane 1, wild-type dTTP, dCTP and dATP; lane 2, COMPOUND XI; lane 3; COMPOUND XI and compound III; lane 4, COMPOUND XI, compound III and dATP; lane 5, COMPOUND XI, compound III and compound XIII. The results show that it is possible to incorporate at least three different nucleotide derivatives after each other using a polymerase. Consequently, the polymerase allows various nucleotide derivatives simultaneously in the active site without a significant reduction of the catalytic activity.

Example 68: Polymerase incorporation of various nucleotide derivatives.

[0642] An extension primer (5'-TCC GCT ACT GGC ATC GGT-3') was 5'-labeled with ^{32}P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). This extension primer was annealed with a template primer (5'-TGA ACC GAT GCC AGT AGC-3') using 0.1 and 3 pmol respectively in the extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl_2 , pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooled to about 20 °C. This template primer was 3'Biotin-C6-labeled to prevent extension. The nucleotide derivatives was then added (about 100 μM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. The samples were mixed with formamide dye and run on a 10% urea polyacrylamide gel electrophoresis. The gel was developed using autoradiography (Kodak, BioMax film). Figure 53 show the incorporation of various nucleotide derivatives compared to wild type nucleotides. Lane 1, wild-type dCTP, dTTP and dATP; lane 2, compound II, compound III and compound XIII. The results show that it is possible to incorporate at least three different nucleotide derivatives after each other using a polymerase. Consequently, the polymerase allows various nucleotide derivatives simultaneously in the active site without a significant reduction of the catalytic activity.

Examples 69 to 74: Preparation of polymerase mediated templated moleculesExample 69 Crosslinking of encoded amino groups by urea-bond formation.

[0643] A primer (5'-TCC GCT ACT GGT ATC GGX-3') where X denotes deoxy-thymidine-C6- NH_2 , (Glen research, cat #10-1039-90) was 5'-labeled with ^{32}P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103) and purified by micro-spin gel filtration. This primer (0.1 pmol) and 2 pmol of a second primer (5'-XCA CTT GCA GAC AGC- 3') were co-annealed with 1 pmol template primer (5'-GCT GTC TGC AAG TGA CCG ATG CCA GTA GC-3') in a hybridisation-buffer (20 mM Hepes, 200 mM NaCl, pH 7.5) by heating to 80 °C for 2 min. and then slowly cooled to about 20 °C. Subsequently, 10 mM of *N,N'*- CarbonylDiimidazole (Sigma-Aldrich) was added and the samples incubated at 30 °C for 2 hours. The samples were mixed with formamide dye and run on a 10% urea polyacrylamide gel electrophoresis. The gel was developed using autoradiography (Kodak, BioMax film). A schematic description of this experiment is shown below:

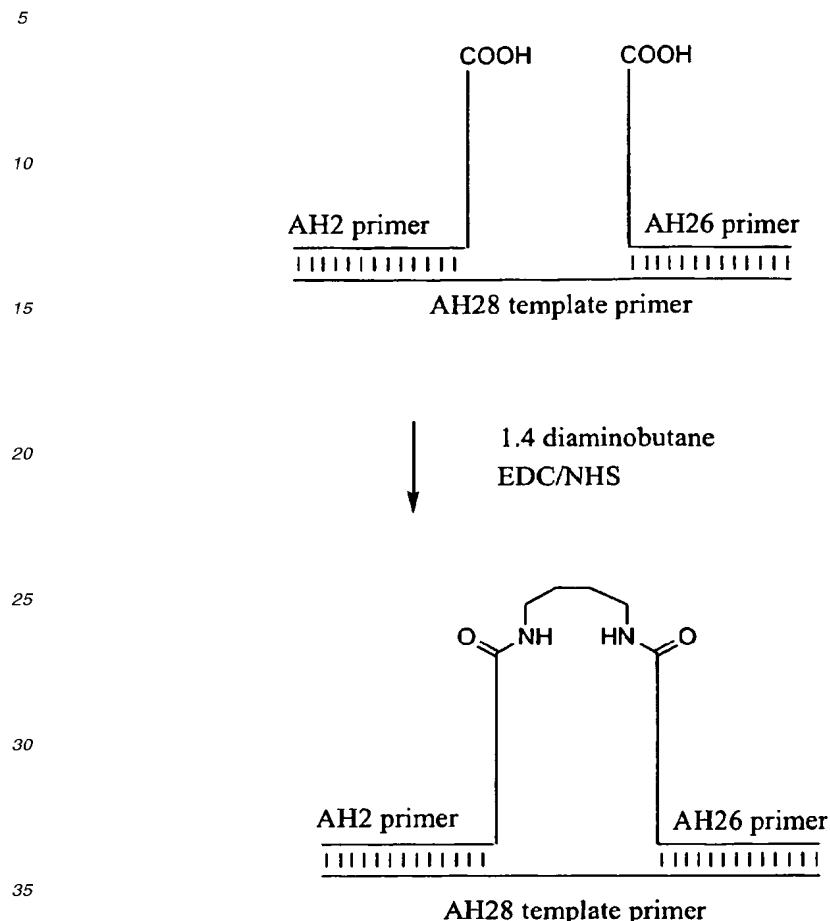

Cross-linking by urea-bond formation

[0644] The results shows that adjacent NH₂-groups can form a covalent urea-bond by the reaction with CDI. No reaction is observed in the absence of a template sequence which shows that the reaction is dependent on the close proximity of NH₂-groups guided by the template sequence. Urea bond formation was also observed when 0.5% formaldehyde was used as cross-linking reagent (data not shown).

Example 70: Formation of amide bonds by a "fill-in" reaction using a di-amino linker.

[0645] In this experiment DNA-encoded Carboxylic acids are cross-linked by a 1,4 diaminobutane. A primer (5'-TCC GCT ACT GGT ATC GGY-3') where Y denotes deoxythymidine-C2-COOH (Glen research, cat #10-1035-90), was 5'-labeled with ³²P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103) and purified by microspin gelfiltration. This primer (0.1 pmol) and 2 pmol of a second primer (5'-YCA CTT GCA GAC AGC- 3') were co-annealed with 1 pmol template primer (5'-GCT GTC TGC AAG TGA CCG ATG CCA GTA GC-3') in a hybridisation-buffer (20 mM Hepes, 200 mM NaCl, pH 7.5) by heating to 80 °C for 2 min. and then slowly cooled to about 20 °C. Subsequently, 100 mM EDC (Sigma-Aldrich), 10 mM N-hydroxysuccinimide (NHS, Sigma-Aldrich) and 10 mM 1,4 diaminobutane (Merck) was added and the samples incubated at 30 °C for 2 hours. The samples were mixed with formamide dye and run on a 10% urea polyacrylamide gel electrophoresis. The gel was developed using autoradiography (Kodak, BioMax film). A schematic description of this experiment is below:

Cross-linking by "fill-in" reaction

[0646] The results show that encoded COOH-groups can be covalently coupled by a bifunctional linker upon formation of amide bonds. No reaction is observed in the absence of a template sequence which shows that the reaction is governed by the proximity of COOH-groups provided by the template sequence. Similar results were obtained using other diamino-linkers such as 1.6 diamino-hexane, spermine and spermidine (data not shown).

Example 71: Polymerase incorporation of nucleotide derivatives and cross-linking to templated anchor-points.

[0647] An extension primer (5'-GCT ACT GGC ATC GGT-3') was 5'-labeled with ^{32}P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). This extension primer was annealed with a template primer (5'-GCT GTC TGC AAG TGA TAA CCG ATG CCA GTA GC-3') using 0.1 and 3 pmol respectively in the extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl_2 , pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooled to about 20 °C. The nucleotide derivatives were then added (about 100 μM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. The oligonucleotide complexes were then purified using micro-spin gel filtration (BioRad). A second primer (5-YCA CTT GCA GAC AGC-3') where Y denotes the anchor-point reactive group deoxythymidine-C2-COOH, was annealed to the extension complex. The buffer composition was adjusted to 20 mM HEPES-KOH, 200 mM NaCl, pH=7,5. Cross-linking was performed using 100 mM EDC and 10 mM N-hydroxysuccinimid for about 2 hours at 30 °C. Relevant samples were subjected to alkaline hydrolysis (0.1 M NaOH, 50 °C for 15 minutes). The samples were mixed with formamide dye and run on a denaturing 10% urea polyacrylamide gel. The gel was developed using autoradiography (Kodak, BioMax film). A schematic outline of this experiment is shown below:

Linking by direct coupling and translocation of a β -Amino acid

[0648] The results show that a reactive group from a nucleotide derivative incorporated by a polymerase can be cross-linked to an anchor point reactive group by a "fill-in" reaction forming amide bonds. Furthermore, the ester linker of the nucleotide derivative is specifically cleaved which allows for the transfer of a templated functional entity to a templated second entity (anchor point).

Example 72: Polymerase incorporation of nucleotide derivatives and cross-linking to a templated anchor-point by a "fill-in" reaction.

[0649] An extension primer (5'-GCT ACT GGC ATC GGT-3') was 5'-labeled with ^{32}P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). This extension primer was annealed with a template primer (5'-GCT GTC TGC AAG TGA TAA CCG ATG CCA GTA GC-3') using 0.1 and 3 pmol respectively in the extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl_2 , pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooled to about 20 °C. The compound II (nucleotide derivative) was then added (about 100 μM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. The oligonucleotide complexes were then purified using micro-spin gel filtration (BioRad). A second primer (5'-XCA CTT GCA GAC AGC-3') where X denotes the anchor-point reactive group deoxythymidine-C6- NH_2 , was annealed to the extension complex. Cross-linking was performed using 10 mM BS_3 [Bis(sulfonylsuccinimide)suberate] (Pierce, cat# 21580) for about 2 hours at 30 °C. Relevant samples were subjected to alkaline hydrolysis (0.1 M NaOH, 50 °C for 15 minutes). The samples were mixed with formamide dye and run on a denaturing 10% urea polyacrylamide gel. The gel was developed using autoradiography (Kodak, BioMax film). A schematic outline of this experiment is shown below:

Linking by "fill-in" and β -Amino acid translocation

[0650] A copy of the gel is shown in Figure 54. Lane 1: no nucleotides, lane 2: dTTP, lane 3: compound I, lane 4: dTTP followed by alkaline hydrolysis, lane 5: compound I followed by alkaline hydrolysis, lane 6: dTTP followed by BS₃ cross-linking, lane 7: compound I followed by BS₃ cross-linking, lane 8: dTTP followed by BS₃ cross-linking and alkaline hydrolysis, and lane 9: compound I followed by BS₃ cross-linking and alkaline hydrolysis. The results show that a reactive group from a nucleotide derivative incorporated by a polymerase can be cross-linked to an anchor point reactive group by a "fill-in" reaction forming amide bonds. Furthermore, the ester linker of the nucleotide derivative is specifically cleaved which allows for the transfer of a templated functional entity to a templated second entity (anchor point).

Example 73: Polymerase incorporation of two nucleotide derivatives and the cross-linking between 3 encoded entities.

[0651] An extension primer (5'-GCT ACT GGC ATC GGT-3') was 5'-labeled with ³²P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). This extension primer was annealed with a template primer (5'-GCT GTC TGC AAG TGA GTA CCG ATG CCA GTA GC-3') using 0.1 and 3 pmol respectively in the extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl₂, pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooled to about 20 °C. The nucleotide derivative V and X was then added (about 100 μM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. The oligonucleotide complexes were then purified using micro-spin gel filtration (BioRad). A second primer (5-YCA CTT GCA GAC AGC-3') where Y denotes the anchor-point reactive group deoxythymidine-C2-COOH, was annealed to the extension complex. The buffer composition was adjusted to 20 mM HEPES-KOH, 200 mM NaCl, pH = 7.5 before addition of 100 mM EDC and 10 mM N-hydroxysuccinimid. This results in the cross-linking of NH₂-groups of MG91 and the COOH group of V and the COOH of the second primer. Suitable samples were subjected to alkaline hydrolysis (0.1 M NaOH 50 °C, 15 minutes). Formamide dye was added to the samples before loading on a 10 % Urea polyacrylamide gel. The gel was developed using autoradiography (Kodak, BioMax film). A schematic representation of this experiment is shown below:

Linking of 3 encoded functional entities

[0652] This result shows that three encoded functional entities can be cross-linked. Furthermore, a specific linker can be selectively cleaved.

Example 74: Polymerase incorporation and β -amino acid translocation ("Zipping").

[0653] An extension primer (5'-GCT ACT GGC ATC GGT-3') was 5'-labeled with ^{32}P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). This extension primer was annealed with a template primer (5'-TAG ACC GAT GCC AGT AGC) using 0.1 and 3 pmol respectively in the extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl_2 , pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooled to about 20 °C. The nucleotide derivatives II and III was then added (about 100 μM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. The oligonucleotides were then purified using micro-spin gel filtration (BioRad) followed by lyophilization. The oligonucleotide complex was dissolved in pyridine and Scandiumtrifluoromethanesulphonate (catalyst) in pyridine was added to a final concentration of 10 mM and the reaction mixture incubated at 50 °C for 1 hour. Relevant samples were subjected to alkaline hydrolysis using 0.1 M NaOH at 50 °C for 15 min. Formamide dye was added to the samples before loading on a 10 % Urea polyacrylamide gel. The gel was developed using autoradiography (Kodak, BioMax film). A schematic representation is shown below:

Zipping and translocation of a β -Amino acid

[0654] The results show that a reactive group of a functional entity can react with a reactive group of an other functional entity forming an amide bond. The reaction results in a translocation of a functional entity onto a second functional entity with simultaneous cleavage of the linker connecting the first functional entity and the nucleotide derivative that encode said functional entity. In this experimental set-up a di-peptide comprising two β -amino acids is produced. Thus, incor-

poration on a DNA template of several (3 or more) nucleotide derivatives comprising β -amino-acids as functional entities would allow multiple translocation events producing β -peptides acids comprising 3 or more β -amino acids. In this example the reaction between functional entity reactive groups occurs in non-aqueous environment. In a preferred aspect the reaction between functional entity reactive groups occurs directly upon incorporation of a nucleotide derivative comprising said function entity by a "zipping" reaction. This can be accomplished by increasing the reactivity of the ester linkage by introducing various chemical entities such as thioesters, phenolic esters, thiophenolic esters, di-, tri- or tetra-fluoro-activated phenolic- or thiophenolic esters or N-hydroxysuccinimide esters.

Example 75: *in silico* experiment A structural description of a template-displayed molecule created using polymerase incorporation of nucleotide derivatives.

[0655] One aspect of the present invention utilizes a suitable polymerase for specific incorporation of nucleotide derivatives on a DNA template. This incorporation is accomplished using a template containing coding elements. The template is utilized by the polymerase to incorporate the nucleotide derivatives in a specific order based on these coding elements (Figure 55). This process is specific due to the recognition groups in the nucleotide derivatives.

[0656] The different nucleotides are modified at specific positions (e.g. Figure 9) to permit incorporation by the polymerase and at the same time expose the linked functional entities in or outside the major groove of the DNA strand exposed to the solvent as shown in Figure. 55A. The consecutive incorporation of the nucleotide derivatives by the polymerase will allow various reactions to occur between the linked functional entities. The reactions are determined by the type of reactive groups integrated in each functional entity (examples shown in Figure 11-21). In addition, the DNA template will arrange the functional entities in specific geometry dependent on the helical structure of the DNA template. This geometry can for example be controlled by different types of linkers that join the functional entity and complementing element. Thus, the linker is designed to favour the reaction between the reactive groups on the nucleotide derivatives. The linker design will differ dependent on which type and how the reactive groups are arranged in the functional entities. The linker can also be designed to guide the reaction between the reactive groups in a specific direction. Various reactive groups can also be used to direct the reaction between the reactive groups. The close proximity and the optimized geometry of the nucleotide derivatives will drastically enhance the reaction rate between the reactive groups in the different functional entities. The reaction rate between the reactive groups is fast due the high local concentration of the incorporated nucleotide derivatives on the DNA template molecule compared to if they were allowed to diffuse freely in solution.

[0657] Figure 55A shows one example where nucleotide derivatives Compound II, compound X and compound V are incorporated by a polymerase after each other on the same DNA template. The synthesis of these nucleotide derivatives are described in detail above. The experimental data showing AMV Reverse transcriptase incorporation of these nucleotide derivatives can be seen in example 64. These incorporated nucleotide derivatives are structurally arranged, by the linker connecting the complementing element and the functional entity, to promote reaction between the reactive groups on each nucleotide derivatives. The distance between the amine in compound II and the COMPOUND X amine in the long side chain is calculated to be between 3.1 Å and 17.5 Å and the distance between the amine in compound II and the COMPOUND X amine in the short side chain to be between 3.0 Å and 14.6 Å dependent on the precise orientation of the linker and the functional entity on the DNA template. The distance between the carbonyl carbon in nucleotide derivative compound V and the long side chain amine in nucleotide derivative COMPOUND X is between 4.2 Å and 19.8 Å and the distance to the short side chain COMPOUND X amine is calculated to be between 3.7 Å and 16.5 Å also dependent of the precise orientation. The close proximity of the nucleotide derivatives compound II, COMPOUND X and 1973 on the DNA template will promote a chemical linkage of the reactive groups in these nucleotide derivatives.

[0658] These three nucleotide derivatives can be linked together through their reactive groups using various chemical reagents. One possible reagent to use is BS₃ [Bis(sulfonylsuccinimide)suberate] (Pierce, cat# 21580). Typically a concentration of about 0.25 - 10 mM is used of this analog. This reagent will cross-link two amines between nucleotide derivatives compound II and COMPOUND X. This particular reagent will insert a spacer of eight carbons between the reactive groups and is capable of bridging a distance of 11.2 Å in the extended conformation. Thus, the BS₃ linker is capable of linking the amines of compound II and either of the amines of compound X. There are other reagents that could be used (longer or shorter) to obtain almost any type of spacers between the reactive amine groups. The carboxylic acid on nucleotide derivative compound V and one of the amines on nucleotide derivative COMPOUND X can be linked together using for example 1-Ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) and N-Hydroxysuccinimide (NHS). This reaction will make a direct connection between the reactive groups on nucleotide derivatives COMPOUND X and compound V. These two reactions result in a new molecule composed of these nucleotide derivatives covalently attached to each other through the coupling reagents (Fig. 55B). This particular DNA template-mediated molecule is produced using both fill-in (BS₃) and direct coupling (EDC/NHS) chemistry. Examples of cross-linking between incorporated nucleotide derivatives are shown above. Other types of coupling approaches that could be used are zipping by translocation

or ring opening. These coupling strategies need other types of linker design as described in this invention.

[0659] At this stage, all the functional entities are still attached to the DNA template through the linker joining the functional entity and the complementing element. The ester element integrated in the linker of nucleotide derivatives compound II and COMPOUND X can specifically be hydrolysed (see example 65 for experimental details) to liberate the functional entities of these two nucleotide derivatives from the DNA template. This hydrolysis reaction results in a new molecule that is only attached to the DNA template through the linker in the compound V nucleotide derivative (fig. 55C). This molecule can then extend out from the DNA template into the solution and become accessible (displayed) for interaction with other molecules in the solution.

[0660] This templated molecule, as part of a library of many different templated molecules, can finally be used in a selection procedure to identify molecules that bind to various targets. A detailed description of the selection procedure can be found elsewhere herein.

Example (Model) 76: PNA synthesis - base linked

[0661] PNA monomers are linked to complementing elements via cleavable benzyl- or benzyloxycarbonyl moieties bound to the base part of each PNA monomer. A carboxylic acid is used as anchor point to the oligonucleotide complex. Each building block is annealed to a oligonucleotide template (not shown).

Step A: Polymerization

[0662] To an aqueous buffered solution (10 uL, 1 M NaCl, 100-500 mM buffer pH 6-10, preferably 7-9) of oligonucleotide complexes (0.1-100 uM, preferably 0.5-10 uM) is added a peptide coupling reagent (0.1 mM-100 mM, preferably 1-10 mM) exemplified by but not limited to EDC, DCC, DIC, HATU, HBTU, PyBoP, PyBroP or N-methyl-2-chloropyridinium tetrafluoroborate and a peptide coupling modifier (0.1 mM-1 uM, preferably 1-10 mM) exemplified by but not limited to NHS, sulfo-NHS, HOBt, HOAt, or DhbtOH in a suitable solvent (1 uL) e.g. water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile or a mixture of these. Reactions run at temperatures between -20 °C and 60 °C. Reaction times are between 1 h and 1 week, preferably 1 h-24 h.

The above procedure exemplifies the polymerisation on an 11 uL scale, but any other reaction volume between 1.1 uL and 1.1 L may be employed.

Step B: Linker cleavage and deprotection

[0663] Cbz- and Benzyl protective groups may be removed by a variety of methods, [Greene;1999;] Due to its mildness, catalytic reduction is often the method of choice. Combining an insoluble hydrogenation catalyst e.g. Pd/Al₂O₃, Pd/CaCO₃, Pd/C, PtO₂ or a soluble one e.g. Wilkinsons catalyst and a hydrogen source exemplified but not limited to H₂, ammonium formate, formic acid, 1,4-cyclohexadien, and cyclohexene in a suitable solvent like water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile, acetic acid or a mixture of these with the oligo nucleotide complexes removes the Cbz- and benzyl protective groups.

[0665]

Step A, B:

[0666] To a DCM solution (20 mL) of 4-nitrophenylchloroformate (5 mmol) cooled on an ice/water bath is added (4-Ethynylphenyl)methanol (5 mmol) dissolved in DCM (20 mL) dropwise. After 1 h the ice bath is removed. The reaction is monitored by TLC. Upon completion, (6-Aminopurin-9-yl)-acetic acid ethyl ester (5mmol) in pyridine (20 mL) is added and left to react 16h at rt. Volatiles are removed *in vacuo* and the residue purified by chromatography.

Step C, D:

[0667] Steps C[Hyrup;1996; *Bioorganic & medicinal chemistry*; 5-23] and D[Schmidt;1997; *Nucleic Acids Research*; 4792-4796,Böhler;1995; *Nature*;] are known from the literature.

Step E

[0668] A DMF solution (2 mL) of the protected iodo substituted nucleoside (0.34 mmol), the alkyne (0.69 mmol, 2 eq), DIEA (0.25 mL) is purged with Ar for 5 min. Tetrakis triphenylphosphine palladium (0.03 mmol, 0.1 eq) and CuI (0.07 mmol, 0.2 eq) is added and the mixture is heated to 50 °C and kept there for 20 h. Evaporation of volatiles followed by chromatography affords the desired modified nucleoside that is converted into its corresponding phosphor amidite and incorporated into an oligonucleotide.

Example (model) 77: PNA Synthesis - Nitrogen linked

[0669] PNA monomers are linked to complementing elements via cleavable benzyl moieties bound to the base part of each PNA monomer. An amine is used as anchor point to the oligonucleotide complex. Each building block is annealed to a oligonucleotide template (not shown).

[0670]  Designates a valence bond between modified nucleotides.

Step A: Polymerization

[0671] To an aqueous buffered solution (10 μ L, 1 M NaCl, 100-500 mM buffer pH 6-10, preferably 7-9) of oligonucleotide complexes (0.1-100 μ M, preferably 0.5-10 μ M) is added a peptide coupling reagent (0.1 mM - 100 mM, preferably 1-10 mM) exemplified by but not limited to EDC, DCC, DIC, HATU, HBTU, PyBoP, PyBroP or N-methyl-2-chloropyridinium tetrafluoroborate and a peptide coupling modifier (0.1 mM-1 μ M, preferably 1-10 mM) exemplified by but not limited to NHS, sulfo-NHS, HOBt, HOAt, or DhbtOH in a suitable solvent (1 μ L) e.g. water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile or a mixture of these. Reactions run at temperatures between -20 $^{\circ}$ C and 60 $^{\circ}$ C. Reaction times are between 1 h and 1 week, preferably 1 h-24 h.

The above procedure exemplifies the polymerisation on a 11 μ L scale, but any other reaction volume between 1.1 μ L and 1.1 L may be employed.

Step B:

[0672] Cbz- and Benzyl protective groups may be removed by a variety of methods, [Greene and Wuts;1999;] Due to its mildness, catalytic reduction is often the method of choice. Combining an insoluble hydrogenation catalyst e.g.

Pd/Al₂O₃, Pd/CaCO₃, Pd/C, PtO₂, or a soluble one e.g. Wilkinsons catalyst and a hydrogen source exemplified but not limited to H₂, ammonium formate, formic acid, 1,4-cyclohexadien, and cyclohexene in a suitable solvent like water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylen glycol, acetonitril, acetic acid or a mixture of these with the oligo nucleotide complexes removes the Cbz- and benzyl protective groups.

Example 78 (model): Polysaccharides

General scheme for polysaccharide synthesis

[0673]

Step A

[0674] A primer sequence modified with a carboxylic acid (e.g. Glen Research Carboxy-dT cat. No. 10-1035-) that has been attached to a 2-amino-sugar is annealed to a template (not shown) and extended with modified nucleotides carrying hexose units. Pg is a protection group [Seeberger;2000; Chem. Rev.; 4349-4393; Seeberger;2001;] exemplified by but not limited to Ac, Bz, Lev, Piv, Silanes (SiR₃ wherein R is lower alkyl), Lg is a leaving group typical for carbohydrate chemistry exemplified by but not limited to halogen, trichloroacetamidato, mercaptan, phenol, phosphate esters and

sugar nucleoside phosphates or sugar phosphates for enzymatic[*Wong;1994; Tetrahedron Organic Chemistry Series;]* carbohydrate synthesis. Polysaccharides may also be synthesised using glycols.

Step B: Linker Activation

[0675] The ester linkages are cleaved with aqueous hydroxide at pH 9-12 at room temperature, 16 h in a suitable solvent like water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile or a mixture of these. If Pg is Ac or other base labile protective group, these are removed as well.

[0676] Carbohydrates have several OH-functionalities allowing attachment to the complementing element. This example shows a 1-6 coupled trimer but any combination of building blocks may be used. Attaching carbohydrate units to a template may lessen the tendency of these units to fold into secondary structures hence facilitating the synthesis of polysaccharides.

Example (Model) 79: Acrylamide

General scheme for a polyacrylamid synthesis:

[0677]

[0678] A terminally modified primer sequence carrying an iodine atom is annealed to an oligo nucleotide template (not shown) and extended with modified nucleotides carrying N-substituted acrylamide units.

Step A: Polymerisation

[0679] Acrylamides are polymerized in a cascade radical reaction starting by abstraction of the iodine atom by a radical initiator forming a carbon atom based radical.

To an aqueous buffered solution (10 μ L, 1M NaCl, 100-500 mM buffer pH 6-10, preferably 7-9) of oligonucleotide complexes (0.1-100 μ M, preferably 0.5-10 μ M) carrying N-substituted acrylamid units is added a radical initiator (0.1 mM-100mM, preferably 1-10 mM) exemplified by but not limited to peroxy monosulfate, AIBN, di-*tert* butylperoxide, *tert* butylperoxide, hydrogen peroxide or lead acetate in a suitable solvent (1 μ L) e.g. water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile or a mixture of these, optionally applying UV-light, ultrasound or microwaves. Reactions run at temperatures between -20 °C and 100 °C, preferably between 0 °C and 60 °C. Reaction times are between 1 h and 1 week, preferably 1 h-24h.

The above procedure exemplifies the polymerisation on a 11 μ L scale, but any other reaction volume between 1.1 μ L and 1.1L may be employed.

Step B: Activation

[0680] The N-O bond is susceptible to cleavage by reduction using hydrogenation catalysts and a suitable hydrogen source or in the presence of certain metal salts.

[0681] To an aqueous buffered solution (10 μ L, 1M NaCl, 100-500 mM buffer pH 4-10, preferably 4-7) of oligonucleotide complexes (0.1-100 μ M, preferably 0.5-10 μ M) is added reductants (0.1mM-100mM, preferably 1-10 mM) exemplified by but not limited to samarium(II) iodide, tin(II) chloride or manganese(III) chloride in a suitable solvent (1 μ L) e.g. water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile or a mixture of these. Reactions run at temperatures between -20 °C and 100 °C, preferably between 0 °C and 60 °C. Reaction times are between 1h and 1 week, preferably 1h-24h.

The above procedure exemplifies the polymerisation on a 11 μ L scale, but any other reaction volume between 1.1 μ L and 1.1L may be employed.

Building block synthesis:

Step A:

[0682] A DMF solution (20 mL) of the protected iodo substituted nucleoside (3.4 mmol), the alkyne (6.9 mmol, 2 eq, Aldrich P51338), DIEA (2.5 mL) is purged with Ar for 5 min. Tetrakis triphenylphosphine palladium (0.3 mmol, 0.1 eq) and CuI (0.7 mmol, 0.2 eq) is added and the mixture is heated to 50 °C and kept there for 20 h. Upon cooling, the mixture is added 700 mL diethylether. The organic phase is washed with ammonium chloride (sat, aq, 250 mL) and water (250 mL). Evaporation of volatiles followed by stripping with toluene (400 mL) affords the desired modified nucleoside that is purified by column chromatography (silica gel, Heptane/Ethyl acetate eluent).

Step B:

[0683] To the modified nucleoside obtained in Step A (2 mmol) in ethanol (30 mL) is added hydrazine hydrate (400 mg, 8 mmol, 4 eq.) and the mixture is stirred at 20 °C. The reaction is monitored by TLC. Upon completion volatiles are removed *in vacuo* and the residue purified by chromatography.

Step C:

[0684] The amine obtained in Step B (0.5 mmol) is added DMF (10 mL), benzaldehyde (0.6 mmol, 1.2 eq), acetic acid (100 μL , 1%) and sodium cyanoborohydride (0.6 mmol). Reacts at 20 °C, 16 h and is quenched with NaHCO_3 (aq, 10 mL, 5%) and extracted with ethyl acetate (3x100 mL). The combined organic phase is washed with NH_4Cl (sat, aq, 50 mL) and water (50) mL and dried over Na_2SO_4 . Upon evaporation of ethyl acetate, the residue may be purified by chromatography.

Step D:

[0685] The product obtained in Step C (0.1 mmol) is dissolved in dichloromethane in the presence of 2,6-di *tert*-butylpyridine (0.4 mmol) and cooled to 0 °C where acrylchloride (0.15 mmol) in dichloromethane (2 mL) is added dropwise.

Upon 1h reaction at 0 °C the temperature is allowed to raise to 20°C and the reaction is quenched after 1h with NaHCO₃ (aq, 3 mL, 5%). The phases are separated and the organic phase reduced under vacuum. The residue is taken up in ethyl acetate and is washed with HCl(aq) (0.1 M, 3 mL), NaHCO₃ (aq, 3 mL, 5%) and water (3 mL). Upon evaporation of ethyl acetate, the product is stripped with toluene (2x20 mL), purified by chromatography and converted into the desired building block type, e.g. a 5'-triphosphate.

Example (Model) 80: Synthesis of β -peptides

[0686]

General scheme for β -peptide synthesis:

Step A

[0687] The amine precursor may be an amine carrying a protective group [Greene and Wuts; 1999;] exemplified by but not limited to benzyl carbamate, paramethoxybenzyl carbamate, 2-Trimethylsilylethyl carbamate, 2,2,2-Trichloroethyl Carbamate. These protective groups are removed by hydrogenolysis, mild acid treatment, fluoride treatment and treatment with Zn dust respectively. Alternatively, the amine precursor may be a nitro group or an azide. Both are converted into amines by reduction. The latter is also reduced under mild conditions using phosphines.

Step B

[0688] The free amine generated in step A attacks the neighbouring NTA unit to start the cascade.

Step C

[0689] Linker cleavage is carried out using UV radiation (250-500 nm) on a buffered solution of oligonucleotide complexes (pH 5-10) to partially release a beta peptide.

Example (Model) 81: β -peptoid synthesis

[0690]

General scheme for β -peptoid synthesis

Step A

[0691] The amine precursor may be an amine carrying a protective group [Greene and Wuts; 1999;] exemplified by but not limited to benzyl carbamate, paramethoxybenzyl carbamate, 2-Trimethylsilylethyl carbamate, 2,2,2-Trichloroethyl Carbamate. These protective groups are removed by hydrogenolysis, mild acid treatment, fluoride treatment and treatment with Zn dust respectively. Alternatively, the amine precursor may be a nitro group or an azide. Both are converted into amines by reduction. The latter is also reduced under mild conditions using phosphines.

Step B

[0692] The free amine generated in step A attacks the neighbouring [1,3]Oxazinan-6-one unit initially forming an unstable aminal due to the ring opening. This collapses to an aldehyde releasing a secondary amine which is now able to continue the cascade resulting in this case in a beta peptoid.

10

20

25

30

35

40

50

55

145

Step B: Di-amine protection

[0695] 1,3-Diamino-propan-2-ol (1 mmol) and trifluoroacetic anhydride (2 mmol) is mixed in diethylether at 0 °C and left to react at this temperature 4h. The reaction mixture is extracted with 1M HCl, NaHCO₃ (aq) and water. The product is obtained by evaporation of the organic phase

Step C: Carbamate formation

[0696] 2,2,2-Trifluoro-N-[2-hydroxy-3-(2,2,2-trifluoro-acetyl-amino)-propyl]-acetamide (1.5 mmol) obtained in step B is dissolved in THF along with chlorosulfonyl isocyanate (1.5 mmol) and left to react at 20 °C, 16h. The crude product is used without purification.

**Step D: Reductive amination**

[0697] The aldehyde (5 mmol) is dissolved in a minimum MeOH and added an amine (6 mmol), sodium cyanoborohydride (6 mmol) and acetic acid. Upon stirring overnight volatiles are removed and the product is purified by crystallisation or chromatography.

Step E: Sulfonamide formation

[0698] The crude product from step A or step C in THF is added to the amine obtained in step D in a water/THF mixture in the presence of base and left to react at 20 °C, 4h. Then the mixture is refluxed over night. Upon cooling, the solvent is removed and the residue purified by chromatography.

**Oligo building block preparation**

[0699] The protected diamines and diacids are attached to modified oligonucleotides carrying a primary amino func-

tionality using EDC and NHS in an aqueous buffer (pH 5-8, preferably 6-7). The protective groups (both methyl esters and trifluoro acetamides) are removed in aqueous buffer (pH 10-12). Alternatively, the protection groups remain on the building blocks and are removed after annealing to the oligonucleotide template.

Library preparation

Polymerisation:

[0700] To an aqueous buffered solution (10 μ L, 1M NaCl, 100-500 mM buffer pH 6-10, preferably 7-9) of oligonucleotide complexes (0.1-100 μ M, preferably 0.5-10 μ M) carrying di-amines and di-carboxylic acids is added a peptide coupling

reagent (0.1 mM-100 mM, preferably 1-10 mM) exemplified by but not limited to EDC, DCC, DIC, HATU, HBTU, PyBoP, PyBroP or *N*-methyl-2-chloropyridinium tetrafluoroborate and a peptide coupling modifier (0.1 mM- 100 mM, preferably 1-10 mM) exemplified by but not limited to NHS, sulfo-NHS, HOBt, HOAt, DhbtOH in a suitable solvent (1 μ L) e.g. water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile or a mixture of these. Reactions run at temperatures between -20 °C and 60 °C. Reaction times are between 1 h and 1 week, preferably 1 h-24h. The above procedure exemplifies the polymerisation on a 11 μ L scale, but any other reaction volume between 1.1 μ L and 1.1L may be employed.

Activation (Linker cleavage):

[0701] Linkers are cleaved by treatment with acid pH 0-5, at 0-40 °C for 10 min-10 h. **References**

Example (model) 83. Isolation of α -peptide ligand to Glutathione S-transferase (GST) from a library of templated α -peptides.

A) Nucleotide derivative synthesis

[0702] The synthetic strategy for three nucleotide derivatives is shown in the scheme below with a detailed description of the synthesis. Examples of other synthesized α -amino acid nucleotide derivatives can be found in the literature (*e.g.* Ito et al. (1980) *J. Amer. Chem. Soc.* 102: 7535-7541; Norris et al. (1996) *J. Amer. Chem. Soc.* 118: 5769-5803; Celewicz et al (1998) *Pol. J. Chem.* 72: 725-734).

[0703] Synthesis of LH1, LH7: EDC (3.2 mmol) is added to an ice-water cooled solution of either *N*-(*tert*-butoxycarbonyl)-*tert*-butoxy glutamate (3.0 mmol) or *N*-(*tert*-butoxycarbonyl)-glycine (3.0 mmol) in dichloromethane (10 mL). A solution of 4-dimethylamino pyridine (0.3 mmol) and 5-hexynol (4.6 mmol) in dichloromethane (1 mL) is added. The reaction mixture is stirred for 1 h. at 0°C, then at room temperature overnight. Solvent was evaporated off and the residue is taken up in diethyl ether. The slurry is washed with HCl (0.1 M, 25 mL), saturated NaHCO₃ (25 mL) and brine (25 mL), then concentrated to oil. The product is purified by flash-chromatography.

[0704] Synthesis of LH4: 6-iodohexyne (6 mmol) and K₂CO₃ (6 mmol) is added to a solution of *N*-(*tert*-butoxycarbonyl)-cysteine (3 mmol) in methanol (5 mL) and DMF (5 mL). The reaction mixture is stirred for 1 day at 40°C, then concentrated and worked-up by column chromatography.

[0705] Synthesis of LH2, LH5 and LH8: Tetrakis(triphenylphosphine)palladium (0.6 mmol) and CuI (0.2 mmol) is added to a degassed solution of the iodo nucleoside (1 mmol), the alkyne (2 mmol) and ethyldiisopropyl amine (2 mmol) in DMF or ethanol (4 mL). The reaction mixture is stirred under an atmosphere of argon. The reaction was followed by TLC. The reaction is stirred at 50°C if no reaction occurred at room temperature. The reaction mixture is concentrated to syrup and worked-up by RP-HPLC (eluent: water → methanol). The corresponding *tert*-butyldimethyl silyl protected

iodo nucleoside is used instead of the unprotected nucleoside when the primary hydroxyl group is acylated in the course of the reaction. The silyl ether is cleaved after the Sonogashira coupling by treating the compound with tetrabutyl ammonium fluoride (4 eq.) in a solution of ethanol and acetic acid (8 eq.) for 1 day followed by concentration and work-up by RP-HPLC (eluent: water → methanol).

[0706] Synthesis of LH3, LH6 and LH9: Phosphooxychloride (0.11 mmol) is added to an ice-water cooled solution of the nucleoside (0.1 mmol) in trimethyl phosphate (1 mL). The reaction mixture is stirred under an atmosphere of argon at 0°C for 1 h. A solution of bis-n-tributylammonium pyrophosphate (0.2 mmol) in DMF (1 mL) and n-tributylamine (0.3 mmol) is then added. The reaction mixture is stirred for 10 minutes then water (1 mL) was added. The mixture is neutralized with triethylamine and stirred at room temperature for 6 h, then concentrated *in vacuo* and worked-up by ion pair exchange RP HPLC (eluent 100 mM triethylammonium acetate → 100 mM triethylammonium acetate in 80% acetonitrile). Removal of buffer salts from the nucleotide is carried out by adding water (100 µl) to the mixture and then concentrating the slurry at 0.1 mmHg several times finally followed by a gel filtration (eluent: water).

B) Library design and nucleotide derivative incorporation

[0707] A templated library can be produced by extension of a primer annealed to a template primer. The template primer encodes the library and can be prepared using standard procedures, e.g. by organ synthesis with phosphoramidite. To generate various types of oligonucleotide libraries one can for example use redundancies, mixed phosphoramidite or doping in synthesizing the oligonucleotides. These oligonucleotide libraries can be purchased from a supplier making customer defined oligonucleotides (e.g. DNA Technology A/S, Denmark or TAG Copenhagen A/S, Denmark).

[0708] Here, An extension primer (5'-GCT ACT GGC ATC GGT-3') is used together with a template primer (5'-GTA ATT GGA GTG AGC CDD DAC CGA TGC CAG TAG C-3') where D (underlined, using the ambiguity definition from International Union of Biochemistry) is either A, G or T. The extension primer is complementary to the template primer as shown below. During extension the primer is extended past the DDD-sequence, leading to insertion of T-, C-, or A-nucleotide derivatives at there position, according to the sequence of the individual templates. Upon polymerization of the α-amino and precursors attached to the nucleotides, and cleavage of the linker that connect the amino and the nucleotide, a library with a theoretical diversity of at least $3^3 = 27$ different peptides is created.

D = A, G or T

H = T, C or A

[0710] The extension primer is annealed with the template primer, using about 3 pmol of each primer in an extension buffer (20 mM Hepes, 40 mM KCl, 8 mM MgCl₂, pH 7.4, 10 mM DTT), by heating to 80 °C for 2 min and then slowly cooling to about 20 °C. The nucleotide derivatives are then added to a concentration of about 200 µM each, and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. Unincorporated nucleotide derivatives are removed using a spin-column (BioRad). Further extension may be performed by adding wild type dNTP using the same conditions described for the nucleotide derivatives. Alternatively, an oligonucleotide that anneal to the sequence downstream of the DDD sequence is added prior to the extension. The double stranded product is purified and transferred to another buffer (100 mM Na-phosphate buffer, pH 8.0) using a spin-column (BioRad).

C) Polymerization and linker cleavage

[0711] The reactive groups of the incorporated nucleotide derivatives are linked together using 1-Ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC) and N-Hydroxysuccinimide (NHS). This is a routine procedure for covalent coupling amines and carboxyl groups. Examples of coupling conditions are described in the literature (e.g. NHS coupling kit, IAsys, code # NHS-2005).

EDC and NHS are added to the purified double stranded extension product at appropriate final concentrations of about 100 mM and 10 mM, respectively. This reaction is incubated at 30°C for 2-16 hours. Excess linking reagents is removed using a spin column. Hydrolysis of hydrolysable linkers is achieved by incubating the sample at pH 11 (e.g. 0.2 M NaOH) for 15 min at 50 °C.

D) Selection

[0712] One of the possible templated molecules in this particular library, when using nucleotide derivatives LH3, LH6 and LH9, is glutathione (Glu-Cys-Gly). The incorporation, reaction between the reactive groups and cleavage of the linkers to generate glutathione on the DNA template is shown in the scheme below. It is known that glutathione binds specifically and with high affinity to Glutathione S-transferase (GST) and is commonly used for purification of GST-fusion proteins (Amersham Pharmacia Biotech). It is also known that glutathione can be immobilized through the sulfur atom without interfering with the binding to GST. Consequently, it is possible to enrich template-displayed glutathione among other displayed molecules in a library by performing selection against GST as the target molecule. GST can be produced in a recombinant form as described in the literature (e.g. Jemth et al. (1997) Arch. Biochem. Biophys. 348: 247-54) or be obtained from various suppliers (e.g. Sigma, product #, G5524). Alternatively, an antibody against glutathione (e.g. Abcam, product name ab64447 or Virogen, product # 101-A) can be used as the target molecule.

Template-mediated formation of glutathione

[0713] A microtiter plate is coated with about 1 µg streptavidin in a TBS buffer (50 mM Tris-HCl, pH 7.5, 150 mM NaCl) overnight at 4 °C. Remove the streptavidin solution and wash the wells at least six times with TBS buffer. Block the wells with 2% BSA in TBS buffer (other examples of blocking agent that could be used is casein, gelatine, polyvinylpyrrolidone or dried skim milk) for about 30 min. at 37 °C. Wash the plate with TBS buffer at least three times. Add 0.1 µg biotinylated GST to the wells and incubate about 30 min at 20 °C. Remove non-bound biotinylated GST by

washing with TBS buffer at least six times. Biotinylation of GST is performed using sulfo-NHS-LC-biotin as described in the literature (e.g. Ellis et al. (1998) Biochem. J. 335; 277-284). Free streptavidin molecules are blocked with 1 mM biotin for 5 min. and excess biotin is removed by wash with TBS buffer at least six times. Add then the templated molecule library to the wells and allow binding to immobilized GST by incubating at 20 °C for about 1 hour. To remove the templated molecules not coordinated to the immobilized GST, wash the wells with TBS buffer at least six times. Elute the templated molecules bound to GST by incubating with 20 mM reduced glutathione for about 10-60 min and then transfer the samples from the wells to new tubes.

[0714] The eluted (selected) templates are amplified using two amplifying primers (forward, 5'Biotin-GCT ACT GGC ATC GGT-3'; reverse, 5'-GTA ATT GGA GTG AGC-3') with a standard PCR protocol (e.g. 5 pmol of each primer, 0.2 mM of dNTP, 2 mM of MgCl₂, and 2.5 U of thermal stable Taq polymerase). The PCR is performed with an initial denaturation at 94 °C for 5 min, 35 cycles of denaturation at 94 °C for 30 seconds, annealing at 50 °C for 30 seconds, extension at 72 °C for 30 seconds, and then a final extension at 72 °C for 10 min. The 5'biotin in the forward primer is used to remove the sense strand. This is done by incubating the PCR product with streptavidin-coated magnetic beads (Dynabeads; Dynal Biotech, Norway) and the single stranded template is purified as described by the manufacturer. The purified antisense strand is finally used as the template primer together with the extension primer as describe above to generate an enriched library of templated molecules for another round of selection.

[0715] The selection and amplification procedure is repeated until appropriate enrichment is obtained. Enrichment can be followed by characterization (sequencing) of recovered template sequences. The nucleotide sequence of the templates is obtained using standard sequencing protocols and a DNA sequencer (e.g. MegaBase, Amersham Pharmacia Biotech). Enrichment is obtained when the number of sequences coding for glutathione (C-A-T or T-A-C in the D-D-D region of the template primer) has increased relative to other sequences in the library after the selection procedure.

[0716] This protocol describes incorporation of three different mono-nucleotide derivatives. However, all the mono-nucleotides (including dGTP) could be used in building libraries of templated molecules as described above. Still, this will limit the number of different nucleotide derivatives to four and thus put a boundary on the library size to 4^N (where N is the number of subunits in the templated molecule). However, one may use for example di-nucleotide derivatives as building blocks in order to increase the library size to 16^N. Incorporation of di-nucleotides by polymerase has earlier been described (WO 01/16366 A2). Library diversity may be further increased using tri-nucleotides or tetra-nucleotide incorporation.

Examples 84 to 99: Preparation of intermediate compounds for oligonucleotide building block synthesis

General experimental methods.

[0717]

Method 1. General procedure for *N*-trifluoroacetyl protection of amino acids.

[0718] A stirred solution of the amino acid (20 mmol) in CF_3COOH (10 mL) at 0 °C was slowly added $(\text{CF}_3\text{CO})_2\text{O}$ (24 mmol). The reaction mixture was allowed to slowly warm up to RT and left with stirring over night. The reaction mixture was evaporated to dryness. Crude products of solid nature was recrystallized from EtOAc/heptane. Crude products of liquid nature was purified by flash column chromatography ($\text{CH}_2\text{Cl}_2/\text{MeOH}=10:1$ or EtOAc/heptane=2:1). The yield was in general higher than 85%.

Method 2. General procedure for *N*-benzyloxycarbonyl and *N*-vinylloxycarbonyl protection of amino acids.

[0719] A stirred solution or slight suspension of the amino acid (7.6 mmol) in sat. NaHCO_3 (10 mL) was added 2 M NaOH (aq., 3 mL) and then a solution of either benzyloxycarbonylchloroformate or vinylloxycarbonylchloroformate (8.4 mmol) in CH_3CN (10 mL). The reaction mixture was left with stirring at RT over night. When TLC indicated complete transformation, the reaction mixture was added H_2O (90 mL) and pH was adjusted to 10 using 2 M NaOH (aq.). The reaction mixture was washed with Et_2O (3x 50 mL) and pH adjusted to 2-3 using 1 M HCl (aq.) and then extracted using Et_2O or CH_2Cl_2 (3x 100 mL). The combined extractions were dried (MgSO_4), filtered and evaporated to dryness to yield a solid product, which was used without further purification. The yield was in general higher than 70%.

Method 3. General procedure for *N*-*tert*-butyloxycarbonyl protection of amino acids.

[0720] A slight suspension of the amino acid (15 mmol) in H_2O (5 mL) and dioxan (5 mL) was added 2M NaOH (aq, 6 mL). The mixture was cooled and stirred at 0 °C (ice bath), and di-*tert*-butyl dicarbonate was added. Further 2 M aqueous NaOH (4 mL) was added. The mixture was slowly heated to RT (over 5 hours), and left with stirring at RT over night. The reaction mixture was added diethyl ether (20 mL) and pH was adjusted (from ~10 to ~3), using 2 M HCl (aq.). The aqueous phase was extracted, using diethyl ether (3x 20 mL). The combined extracts were dried (MgSO_4), filtered and evaporated to dryness to yield a white solid product, which was used without further purification. The yield was typically 60-75 %.

Method 4. General procedure for formation of NHM esters of *N*-protected amino acids.

[0721] A stirred solution of the *N*-protected amino acid (0.5 mmol) and *N*-hydroxymaleimide (0.62 mmol) in anhydrous THF (5 mL) at 0 °C under N_2 was added diisopropylcarbodiimide (DIC) (0.64 mmol) and the solution allowed to slowly

warm up to RT and left with stirring over night. The reaction mixture was filtered and the precipitate washed with a small volume of EtOAc/heptane=2/1. The filtrate was evaporated to almost dryness, diluted with a minimum of CH_2Cl_2 and subjected to flash column chromatography (EtOAc/heptane=2/1), yielding the product as a white solid in typically 60-70%.

Method 5. General procedure for formation of NHM esters from carboxylic acid chlorides.

[0722] A stirred solution of N-hydroxymaleimide (4 mmol) in CH_2Cl_2 (16 mL) at 0 °C was slowly added the carboxylic acid chloride (4 mmol). The reaction mixture was allowed to slowly warm up to RT and left with stirring over night. The reaction mixture was diluted with CH_2Cl_2 (16 mL) and washed with 10% citric acid (aq., 3x 25 mL), sat. NaHCO_3 (aq., 2x 25 mL) and sat. NaCl (aq., 1x 25 mL). The organic phase was dried (MgSO_4), filtered, and evaporated to dryness to yield the product as a wax or liquid in 40-60% yield. The product was used without further needed purification.

Method 6. General procedure for S-tritylation of mercaptanes.

[0723] A solution of the mercaptane (20 mmol) and pyridine (40 mmol) in CH_2Cl_2 (75 mL) at RT was added tritylchloride (22 mmol) and the reaction left with stirring over night. The volume of the reaction mixture was reduced to a minimum and then subjected to flash chromatography (SiO_2 pretreated with pyridine prior to column packing) (eluent: $\text{CH}_2\text{Cl}_2/\text{MeOH}=10/0.5$). The product was isolated as an oil or a sticky wax in some instances.

Method 7. General procedure for O-acylation of 4-hydroxybenzaldehydes.

[0724] To a stirred solution of the hydroxybenzaldehyde (20 mmol) in dry DMF (10 mL) at 0 °C was slowly added an acid chloride (25 mmol) in diethyl ether (20 mL). The reaction mixture was stirred at 0 °C for 15 minutes and at rt for 1 hr. Water (20 mL) was added and the reaction mixture was extracted with ether (3x10 mL). The combined organic phases was washed with water (2x10 mL), dried over MgSO_4 and the solvent removed *in vacuo*. The crude was redissolved in dichloromethane (5 mL) and filtered through a pad of silica. The solvent was removed *in vacuo*. The yield was in general higher than 75%.

Method 8. General procedure for formation of diaminopolyethyleneglocols.

[0725] The corresponding polyethyleneglycol-diol (0.8 mmol), obtained as described by Baker et al. J. Org. Chem. (1999), 64, 6870-6873, was dissolved in dry THF (10 mL). Tosyl chloride (2.44 mmol) was added and the reaction mixture was cooled on ice. NaOH (5.5 mmol) dissolved in water (2 mL) was added dropwise and the reaction mixture was stirred at rt o/n. The reaction mixture was extracted with diethyl ether (3x5 mL) and the combined organic phases washed with NaCl (sat., 3x3 mL) and dried over MgSO_4 . The crude was redissolved in dry acetonitrile (3 mL) and treated with NaN_3 (2.8 mmol). The reaction mixture was heated to 75 °C o/n. The white solid was filtered off and extracted with acetonitrile (2x2 mL). Triphenylphosphine (2.8 mmol) and water (2 mL) was added to the combined organic phases and the reaction mixture was stirred o/n. IRA-120 H^+ (1g) was added and the reaction mixture was agitated for 1 hour. The

beads were filtered off, washed with dichloromethane (10x3 mL) and the final compound eluted with 6M HCl (aq., 10x3 mL). The solution was evaporated *in vacuo* affording the diamino polyethylene glycol in 40-50% yield.

Example 84: Preparation of 3-phenyl-3-tert-butoxycarbonylamino-propionic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester (XVI)

[0726]

Compound XVI

[0727] The compound was prepared in two steps from the commercially available DL-3-amino-3-phenylpropionic acid by use of method 3 followed by method 4.

¹H-NMR (CDCl₃): 7.28-7.42 (m, 5H(ar)); 6.74 (s, 2H); 5.1-5.3 (m, 2H (NH+CH)); 3.24 (dd, 1 H); 3.13 (dd, 1 H); 1.46 (s, 9H).

Example 85: Preparation of 3-tert-butoxycarbonylamino-butanoic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester

[0728]

compound XVII

[0729] The compound was prepared in two steps from the commercially available DL-3-aminobutyric acid by use of method 3 followed by method 4.

¹H-NMR (CDCl₃): 6.80 (s, 2H); 4.83 (br s, 1H(NH)), 4.05-4.15 (m, 1H); 2.8-2.95 (m, 2H); 1.46 (s, 9H); 2.56 (d, 3H).

Example 86: Preparation of 3-tert-butoxycarbonylamino-propionic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester

[0730]

Compound XVIII

[0731] The compound was prepared in two steps from the commercially available beta-alanine by use of method 3

followed by method 4.

$^1\text{H-NMR}$ (CDCl_3): 6.80 (s, 2H); 5.09 (br s, 1H(NH)); 3.48-3.54 (m, 2H); 2.84 (t, 2H); 1.45 (s, 9H).

Example 87: Preparation of 3-Benzylloxycarbonylamino-3-phenyl-propionic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester

[0732]

Compound XIX

[0733] The compound was prepared in two steps from the commercially available DL-3-amino-3-phenylpropionic acid by use of method 2 followed by method 4.

$^1\text{H-NMR}$ (CDCl_3): 7.55-7.20 (m, 10H); 6.75 (s, 2H); 5.55 (br., 1 H); 5.35-5.25 (m, 1 H); 5.15 (s, 2H); 3.35-3.10 (m, 2H).

Example 88: 3-Phenyl-3-vinylloxycarbonylamino-propionic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester

[0734]

Compound XX

[0735] The compound was prepared in two steps from the commercially available DL-3-amino-3-phenylpropionic acid by use of method 2 followed by method 4.

$^1\text{H-NMR}$ (CDCl_3): 7.45-7.30 (m, 5H); 7.20 (dd, 1H); 6.75 (s, 2H); 5.75-5.60 (br., 1H); 5.30 (q, 1 H); 4.70 (d, 1 H); 4.50 (d, 1H); 3.30-3.15 (m, 2H)

Example 89: Preparation of Tritylsulfanyl-acetic acid 2,5-dioxo-2,5-dihydropyrrol-1-yl ester

[0736]

Compound XXI

[0737] The compound was prepared in two steps from commercially available 2-mercaptoacetic acid by use of method 6 followed by method 4.

¹H-NMR (CDCl₃): 7.45-7.20 (m, 15H); 6.75 (s, 2H); 3.20 (s, 2H).

Example 90: (R)-2-(2,2,2-Trifluoro-acetylamino)-3-tritylsulfanyl-propionic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester (XXII)

[0738]

Compound XXII

[0739] The compound was prepared in three steps from commercially available L-cysteine by use of method 1 followed by method 6 and method 4.

Example 91: Preparation of Acetic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester

[0740]

Compound XXIII

[0741] The compound was prepared in one step from commercially available acetylchloride and N-hydroxymaleimide by use of method 5.

¹H-NMR (CDCl₃): 6.75 (s, 2H); 2.35 (s, 3H).

Example 92: Preparation of Propionic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester

[0742]

Compound XXIV

[0743] The compound was prepared in one step from commercially available propanoylchloride and N-hydroxymaleimide by use of method 5.

¹H-NMR (CDCl₃): 6.75 (s, 2H); 2.65 (q, 2H); 1.80 (t, 3H).

Example 93: Preparation of Butyric acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester

[0744]

Compound XXV

[0745] The compound was prepared in one step from commercially available butanoylchloride and N-hydroxymaleimide by use of method 5.

¹H-NMR (CDCl₃): 6.75 (s, 2H); 2.60 (t, 2H); 1.80 (sxt, 2H); 1.05 (t, 3H).

Example 94: Preparation of S-Trityl-4-mercaptobenzoic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester

[0746]

Compound XXVI

[0747] The compound was prepared in two steps from the commercially available 4-mercaptobenzoic acid, by S-tritylation according to method 6 followed by esterification according to method 4.

¹H-NMR (CDCl₃): 8.75 (d, *J* = 8.8 Hz, 2H), 7.45-7.20 (m, 15H), 7.05 (d, *J* = 8.8 Hz, 2H), 6.80 (s, 2H).

Example 95: Preparation of Tetrakis(aminomethyl)methane tetrahydrochlorid**[0748]****Compound XXVII**

[0749] Tetrakis(aminomethyl)methane tetrahydrochloride was prepared by a slightly modified method compared to Fleischer et al. J. Org. Chem. (1971), 36, 3042-44. Pentaerythritol (2.01 g; 14.76 mmol) was mixed with tosyl chloride (14.07 g; 73.81 mol) in dry pyridine (50 mL). The mixture was stirred o/n. The crude reaction mixture was transferred to water (100 mL). MeOH (200 mL) and HCl conc. (80 mL) was added and the white precipitate was filtered off and washed with water (100 mL) and MeOH (200 mL). LC-MS show pentaerythritol tetratosylate. Pentaerythritol tetratosylate (4.0 g, 5.31 mmol) was dissolved in dry DMF (50 mL) and NaN_3 (3.45 g; 53.1 mmol) was added. The reaction mixture was heated to 100°C o/n. Water (100 mL) was added and the reaction mixture was extracted with diethyl ether (3x100 mL). THF (300 mL) was added and the diethyl ether was removed *in vacuo*. Triphenylphosphine (6.95 g, 26.5 mmol) and NH_3 conc. (25 mL) were added to the THF solution and the reaction mixture was stirred at rt o/n. The solvents were removed *in vacuo*, redissolved in dichloromethane (500 mL) and extracted with 2M HCL (2x150 mL). The aqueous phase was washed with dichloromethane (3x100 mL) and evaporated *in vacuo*. MeOH (20 mL) was added and the white solid was filtered off and washed with MeOH (2x10 mL). Yield 1.12g (76%). $^1\text{H-NMR}$ (D_2O): 3.28 (s).

Example 96: Preparation of Propionic acid 4-formyl-phenyl ester**[0750]****Compound XXVIII**

[0751] The compound was prepared according to method 7 from commercially available 4-hydroxybenzaldehyde. $^1\text{H-NMR}$ (CDCl_3): 10.00 (s, 1H), 7.90 (d, $J = 6.7$ Hz, 2H), 7.31 (d, $J = 6.7$ Hz, 2H), 2.65 (q, $J = 7.6$ Hz, 2H), 1.32 (d, $J = 7.5$ Hz, 3H).

Example 97: Preparation of Butanoic acid 4-formyl-phenyl ester**[0752]**

Compound XXIX

[0753] The compound was prepared according to method 7 from commercially available 4-hydroxybenzaldehyde. ¹H-NMR (CDCl₃): 9.95 (s, 1H), 7.94 (d, J = 6.7 Hz, 2H), 7.28 (d, J = 6.7 Hz, 2H), 2.55 (t, J = 7.6 Hz, 2H), 1.80 (q, J = 7.6 Hz, 2H), 1.00 (d, J = 7.5 Hz, 3H).

Example 98: Preparation of 3,6,9,12,15,18,21,24,27,30,33-undecanoxapentatriacontane-1,35-diamine

[0754]

Compound XXX

[0755] Prepared according to method 8 in 48% yield. MS-H⁺ = 545.2 (expected MS-H⁺ = 544.6)

Example 99: Preparation of 3,6,9,12,15,18,21,24,27,30,33,36,39-Tridecanoxahentetracontane-1,41-diamine

[0756]

Compound XXXI

[0757] (05028) Prepared according to method 8 in 40% yield. MS-H⁺ = 633.3 (expected MS-H⁺ = 632.8).

Example 100: Design and testing of oligonucleotide linkers carrying zipper boxes.

[0758] Experiments 100-1 to 100-4 were performed in order to test the efficiency of different designs of zipper boxes. The data obtained follow immediately below, then follows a discussion of the data.

Materials.Buffers.

5 [0759]

Buffer A (100 mM Hepes pH= 7,5, 1 M NaCl)

Buffer B: (100 mM NaPO₄ pH=6, 1 M NaCl)

Buffer C: (100 mM NaBorate pH=9, 1 M NaCl)

10 Buffer D: (100 mM NaBorate pH=10, 1 M NaCl)

Buffer E: (500 mM NaPO₄ pH=7, 1 M NaCl)Buffer F: (500 mM NaPO₄ pH=8, 1 M NaCl)Annealing of DNA oligonucleotides.

15 [0760] Mix oligos in relevant buffer and heat at 80° C then cool to 28° C (-2° C/30 sek).

5'-Labeling with ³²P.20 [0761] Mix 200 pmol oligonucleotide, 2 µl 10 x phosphorylation buffer (Promega cat#4103), 1 µl T4 Polynucleotid Kinase (Promega cat#4103), 1 µl γ-³²P ATP, H₂O ad 20 µl. Incubate at 37°C , 10-30 minutes.PAGE (polyacrylamide gel electrophoresis).

25 [0762] The samples are mixed with formamide dye 1:1 (98% formamide, 10 mM EDTA, pH 8, 0,025 % Xylene Cyanol, 0,025% Bromphenol Blue), incubate at 80°C for 2 minutes, and run on a denaturing 10% polyacrylamide gel. Develop gel using autoradiography (Kodak, BioMax film).

[0765] Mix 2 μ l buffer B, 5 μ l Ah36 (0,4 pmol/ μ l), 1 μ l Ah37 (2 pmol/ μ l), 1 μ l Ah38 (2 pmol/ μ l), 1 μ l H₂O.
Mix 2 μ l buffer B, 5 μ l Ah36 (0,4 pmol/ μ l), 1 μ l Ah37 (2 pmol/ μ l), 2 μ l H₂O. Anneal by heating to 80° C, then cool to 44° C (-2° C/30 sek).
Add 1 μ l 100 mM NHS and 1 μ l 1 M EDC. Incubate at indicated temperatures (see below) for 45 minutes, then add 2 μ l Buffer D. Incubate for about 2 h, and then analyze by 10% urea polyacrylamide gel electrophoresis.

Incubation temperatures:

[0766] 45 °C, 48,2 °C, 53,0 °C, 58,5 °C, 63,1 °C, 65,6 °C

Experiment 100-2 (Figure 57, A and B):

[0767] Mix 2 μ l buffer B, 1 μ l Ah36 (2 pmol/ μ l), 1 μ l Ah51 (2 pmol/ μ l), 1 μ l Ah38(2 pmol/ μ l), 5 μ l H₂O.
Mix 2 μ l buffer B, 1 μ l Ah36 (2 pmol/ μ l), 1 μ l Ah51 (2 pmol/ μ l), 6 μ l H₂O
Anneal by heating to 80°C, then cool to 35° C (-2° C/30 sek)(For temperatures 1 to 6), or heat to 80°C, then cool to 15° C (-2° C/30sek)(For temperatures 7 to 12).
Add 1 μ l 100 mM NHS and 1 μ l 1 M EDC. Incubate at indicated temperatures (see below) for 1 h, then add 2 μ l Buffer D. Incubate for 1 h, , and then analyze by 10% urea polyacrylamide gel electrophoresis, as described above.

Incubation temperatures:

[0768] 1) 34,9°C, 2) 36,3°C, 3) 40,3°C. 4) 45,7°C, 5) 51,0°C, 6) 55,77, 7) 14,9°C, 8) 17,8°C, 9) 22,7°C, 10) 28,3°C, 11) 31,0°C, 12) 36°C

[0769] Mix 2 μ l buffer B, 0,5 μ l Ah36 (2 pmol/ μ l), 1 μ l Ah51 (2 pmol/ μ l), 1 μ l Ah38(2 pmol/ μ l), 5,5 μ l H₂O
Mix 2 μ l buffer B, 0,5 μ l Ah36 (2 pmol/ μ l), 1 μ l Ah51 (2 pmol/ μ l), 6,5 μ l H₂O Anneal by heat at 80° C then cool to 5° C (-2° C/30 sek).

Add 1 μ l 100 mM NHS and 1 μ l 1 M EDC. Incubate at different temperatures (see below) for 1 h, then add 2 μ l Buffer D. Incubate for 1 h, , and then analyze by 10% urea polyacrylamide gel electrophoresis.

Incubation temperatures:

[0770] 1) 5,9°C, 2) 9,9°C, 3) 12,6°C, 4) 18,3°C, 5) 23,3°C, 6) 27,9°C 7) 35,6°C, 8) 45,9°C

Experiment 100-3 (figure 58, A and B).

[0771] Mix 2 µl buffer A, 1 µl relevant oligo 1 (2 pmol/ul), 1 µl relevant oligo 2 (10 pmol/ul), 1 µl relevant oligo 3 (10 pmol/ul), 5 µl H₂O. (See table below). Anneal as described above.

Add 1 µl 100 mM NHS and 1 µl 1 M EDC. Incubate at different temperatures 1) 7,7°C, 2) 15,4°C, 3) 21,0°C 4) 26,2°C for about 2 h, and 5) 10°C for 1 sec. , then 35°C for 1 sec. - repeat 99 times. Analyze by 10% urea polyacrylamide gel electrophoresis.

Experiment	Oligo 1 (³² P)	Oligo 2	Oligo 3
100-3-1	Ah36	None	Ah38
100-3-2	Ah36	None	None
100-3-3	Ah36	Ah51	Ah38

100-4-6	Ah36	Ah66	None
100-4-7	Ah65	Ah37	Ah38
100-4-8	Ah65	Ah37	None

Discussion of the results

[0773] The cross-linking efficiency using oligos carrying reactive groups (amine or carboxylic acid) where the linker connecting the reactive group and the annealing region was approximately 25 nucleotides, was examined.

[0774] In an experiment oligonucleotides Ah36 (carrying a carboxylic acid) and Ah67 (carrying an amine) were used. The template used (Ah38) anneals the two oligonucleotides immediately adjacent, i.e. with a spacing of zero base pairs. Under the conditions of the experiment, less than 5% cross-linking efficiency is observed, and only at the highest tested temperature (figure 58, A and B, lanes 5).

[0775] In order to improve the cross-linking efficiency, we introduced a so-called zipper box sequence at the 5'- and 3' end of oligos Ah67 and Ah36, respectively, the same termini that carries the reactive groups. The zipper-boxes are complementary sequences, and thus may bring the reactive groups of the two oligos into closer proximity. Two different lengths of zipper boxes were tested, namely a 10'mer zipper box (Ah37/Ah36 forming a DNA duplex of 10 base pairs) and a 5'mer zipper box (Ah36/51 forming a DNA duplex of 5 base pairs). See figure below.

[0776] Moreover, different designs of zipper boxes were tested, e.g. oligos in which the reactive group is attached immediately adjacent to the zipper box (Ah36, Ah37 and Ah36/Ah51), or placed two nucleotides upstream from the zipper box (Ah65/Ah66), or placed in the middle of the zipper box (Ah67).

[0777] We first tested the effect of the 5' mer zipper box on cross-linking efficiency. As can be seen, the 5' mer zipper box improves the cross-linking efficiency dramatically (figure 58, A and B, compare lanes 3 and lanes 5). Note that the template is absolutely required for cross-linking at all temperatures tested. The highest cross-linking efficiency is obtained when the temperature is cycled 99 times up and down between 10°C and 35°C (figure 58B). A high efficiency is also obtained when the temperature is kept constant at 21°C or 26°C (figure 58A and B, lanes 3). The cross-linking efficiency does not improve further at temperatures above 26°C (figure 57, A and B).

[0778] We next tested the efficiency of cross-linking in the 10' mer zipper box format. Oligos Ah36 and Ah37 were annealed to template Ah38, and the cross-linking efficiency examined at various temperatures. A surprisingly high degree of cross-linking in the absence of template was observed (figure 55, 45°C and 48.2°C). However, at temperatures above 58.5°C, no cross-linking is observed in the absence of template.

[0779] Next, the different locations of the reactive groups relative to the zipper box was tested. As shown in figure 58, A and B, lanes 7, the cross-linking efficiency decreases dramatically when one of the two reactive groups is located in the middle of the zipper box (i.e., the reactive group is attached to a nucleotide involved in DNA double helix formation; Ah67).

[0780] The location of the reactive groups relative to the zipper box was also tested in the context of the 10' mer zipper box. In this context, when both reactive groups are separated from the zipper box by two nucleotides (Ah65, Ah66), the efficiency of cross-linking is slightly decreased (figure 59, compare lanes 1 and 3). The cross-linking efficiency is not changed dramatically when different combinations of Ah65, Ah66, Ah36 and Ah37 are tested (i.e., when the reactive groups are placed immediately next to the zipper box, or two nucleotides upstream). Note that the template is not absolutely required at all temperatures in the context of the 10' mer zipper box. This template-independency is particularly pronounced at lower temperature (e.g., figure 59, 30°C).

Examples 101 to 104: General methods for preparation of oligonucleotide building blocks

Example 101: Procedure for transforming oligonucleotide comprising a carboxylic acid to an amino or aminomethyl terminated linker

[0781] The following oligos containing a modified nucleobase, with a carboxylic acid moiety, were synthesised using the conventional phosphoramidite approach:

A: 5'-GCT ACT GGC XTC GGT

B: 5'-TCA CTX GCA GAC AGC

C: 5'-CGA CCT CTG GAT TGC ATC GGT CAT GGC TGA CTG TCC GTC GAA TGT GTC CAG TTA CX

D: 5'-CTG GTA ACG CGG ATC GAC CTT CAT GGC TGA CTG TCC GTC GAA TGT GTC CAG TTA CX

E: 5'- ACG ACT ACG TTC AGG CAA GAT CAT GGC TGA CTG TCC GTC GAA TGT GTC CAG TTA CX

[0782] X was incorporated using the commercially available carboxy-dT phosphoramidite (10-1035-90 from Glen research). The underlined nucleobases represent the zipper region.

Schematic representation of the transformation

[0783]

[0784] An oligo (20 pmol) was mixed with a diamino compound (20 μ L of a 0.1 M solution), sodiumphosphate buffer (15 μ L of a 100 mM solution, pH=6), NHS (5 μ L of a 100 mM solution) and EDC (5 μ L of a freshly prepared 1 M solution). The mixture was left at 30 °C for 45 minutes and treated with sodium borate (20 μ L of a 100 mM solution, pH=10) and left at 30 °C for additional 45 minutes. The oligo was purified by conventional EtOH precipitation. The products were end-labelled with ³²P and the purity analysed by PAGE. In all cases no starting oligo were detected and a new band, which migrated slower on the gel, appeared.

[0785] Examples of used diamino compounds: XXX, XXXI and the commercially available N,N'-dimethylethylenediamine (D15,780-5 from Sigma-Aldrich).

Example 102: method for transforming a carboxylic acid containing oligonucleotide to a trisamine scaffold building block

[0786] The following oligos containing a modified nucleobase, with a carboxylic acid moiety, were synthesised using the conventional phosphoramidite approach:

F: 5'-GAC CTG TCG AGC ATC CAG CTG TCC ACA ATG X

G: 5'-GAC CTG TCG AGC ATC CAG CTT CAT GGG AAT TCC TCG TCC ACA ATG X

H: 5'-GAC CTG TCG AGC ATC CAG CTT CAT GGG AAT TCC TCG TCC ACA ATG XT

I: 5'-XGT AAC TGG AGG GTA AGC TCA TCC GAA TTC GGT ACT GAC CTG TCG AGC ATC CAG CT

[0787] X was incorporated using the commercially available carboxy-dT phosphoramidite (10-1035-90 from Glen research). The underlined nucleobases represent the zipper region.

Schematic representation of the reaction:

[0788]

[0789] An oligo containing one modified nucleobase with a carboxylic acid moiety (1 nmol) was mixed with water (100 μ L), hepes buffer (40 μ L of a 200 mM, pH=7.5), NHS (20 μ L of a 100 mM solution), EDC (20 μ L of a freshly prepared 1 M solution) and the tetraamine (XXVII) (20 μ L of a 100 mM solution). The reaction mixture was left o/n at room temperature. The volume was reduced to 60 μ L by evaporation *in vacuo*. The pure oligo was obtained by addition of NH_3 conc. (20 μ L) followed by HPLC purification. It was possible to isolate a peak after approximately 6 min using the following gradient: : 0-3 minutes 100% A then 15% A and 85% B from 3-10 minutes then 100% B from 10-15 minutes then 100% A from 15-20 minutes. A = 2% acetonitrile in 10 mM TEAA and B = 80% acetonitrile in 10 mM TEAA.

[0790] After HPLC purification 2-3 pmol was end-labelled with ^{32}P and the purity analysed by PAGE gel (see Figure 60). The PAGE gel show the attachment of the tetraamine (XXVI) to an oligo containing a modified nucleobase with a carboxylic acid moiety.

Lane 1: Reference oligo F.

Lane 2: HPLC purified trisamine product of oligo F.

Lane 3: Reference oligo G.

Lane 4: HPLC purified trisamine product of oligo G.

Lane 5: Reference oligo H.

Lane 6 : HPLC purified trisamine product of oligo H

Example 103: General procedure for attachment of a functional entity to a thio oligo.

[0791] The following oligo containing a modified nucleobase, with a S-triphenylmethyl protected thio moiety, was synthesised using the conventional phosphoramidite approach:

J: 5'-WCA TTG ACC TGT GTA AGC BTG CCT GTC AGT CGG TAC TCG ACC TCT GGA TTG CAT CGG

K: 5'-WCA TTG ACC TGT CTG CCB TGT CAG TCG GTA CTG TGG TAA CGC GGA TCG ACC T

L: 5'-WCA TTG ACC TGA ACC ATG BTA AGC TGC CTG TCA GTC GGT ACT ACG ACT ACG TTC AGG CAA GA

M: 5'-WCA TTG ACC TGA ACC ATG TBA AGC TGC CTG TCA GTC GGT ACT TCA AGG ATC CAC GTG ACC AG

[0792] W was incorporated using the commercially available thiol modifier phosphoramidite (10-1926-90 from Glen research). B is an internal biotin incorporated using the commercially available phosphoramidite (10-1953-95 from Glen research). The nucleobases which are underlined and italic indicates the zipper region.

[0793] The S-triphenylmethyl protected thio oligo (10 nmol) was evaporated *in vacuo* and resuspended in TEAA buffer (200 μ L of a 0.1 M solution, pH=6.4). AgNO_3 (30 μ L of a 1 M solution) was added and the mixture was left at room temperature for 1-2 hours. DTT (46 μ L of a 1M solution) was added and left for 5-10 minutes. The reaction mixture was spun down (20.000 G for 20 minutes) and the supernatant was collected. The solid was extracted with additional TEAA buffer (100 μ L of a 0.1 M solution, pH=6.4). The pure thio oligo was obtained by conventional EtOH-precipitation.

Schematic representation of the reaction:

[0794]

[0795] The thio oligo (1 nmol) was dried *in vacuo* and treated with a building block comprising the functional entity (05087) in dimethylformamide (50 μ L of a 0.1 M solution) and left o/n at rt. The thio oligo was spun down (20.000 G for 10 minutes) and the supernatant removed. Dimethylformamide (1 mL) was added and the loaded thio oligo was spun down (20.000 G for 10 minutes). The dimethylformamide was removed and the loaded thio oligo was resuspended in TEAA buffer (25 μ L of a 0.1 M solution, pH=6.4) and analysed by HPLC.

[0796] Examples of building blocks used: XXVI, XVI, XVII, XVIII, XXIII, XXIV, XXV)

Example 104: General procedure for attachment of a functional entity to an amino or aminomethyl terminated oligo.

[0797] The following oligo containing a modified nucleobase, with an amino group was synthesised, using the conventional phosphoramidite approach:

N: 5'-ZGT AAC ACC TGT GTA AGC TGC CTG TCA GTC GGT ACT GAC CTG TCG AGC ATC CAG CT

[0798] Z contain the modified nucleobase with an aminogroup, incorporated using the commercially available amino modifier C6 dT phosphoramidite (10-1039-90 from Glen research)

[0799] Furthermore, oligo C-E were transformed into the corresponding aminomethyl terminated oligo, as described earlier.

[0800] The oligos were used in the following experiment represented schematically below:

[0801] An amino or aminomethyl oligo (3 pmol) was mixed with a phosphate buffer (3 μ L of a 0.1 M solution, pH=6) and NaBH_3CN (3 μ L of a 1 M solution in MeOH). A building block comprising the functional entity (3 μ L of a 1 M solution in MeOH) was added and the mixture was left o/n at room temperature. The product formation was analysed by PAGE gel (see Figure 61).

[0802] Examples of building blocks used: XXVIII, XXIX, and the commercially available 4-acetoxybenzaldehyde (24,260-8 from Sigma-Aldrich).

[0803] Figure 60 shows a PAGE analysis of the loading of an oligo, containing a modified nucleobase with an amino group (comp. XXIV).

Lane 1 show the reference amino oligo (N).

Lane 2 show the amino oligo (N) after loading with a building block comprising the functional entity.

Lane 3 show removal of the functional entity, attached in lane 2, by treatment with pH=11 for 1 hour.

Example 105: General procedure for the templated synthesis of an organic compound where the scaffold and the substituent are encoded by the template:

[0804]

[0805] The template oligo (1 nmol) was mixed with an thio oligo (L or M) loaded with a functional entity (XXIII or XVII, respectively, 1 nmol) and amino oligo O in hepes-buffer (20 μ L of a 100 mM HEPES and 1 M NaCl solution, pH=7.5) and water (added to a final volume of 100 μ L). The oligos were annealed to the template by heating to 50 °C and cooled (-2 °C/30 second) to 30°C. The mixture was then left o/n at a fluctuating temperature (10°C for 1 second then 35°C for 1 second). The oligo complex was attached to streptavidine by addition of streptavidine beads (100 μ L, prewashed with 2x1 mL 100 mM hepes buffer and 1 M NaCl , pH=7.5). The beads were washed with hepes buffer (1mL). The amino oligo was separated from the streptavidine bound complex by addition of water (200 μ L) followed by heating to 70 °C for 1 minute. The water was transferred and evaporated *in vacuo*, resuspended in TEAA buffer (45 μ L of a 0.1 M solution) and product formation analysed by HPLC (see Figure 62).

[0806] Figure 62 shows the transfer of a functional entity to an oligo containing a modified nucleobase with an amino group.

A) The top chromatogram show the reference amino oligo O: 5'-GAC CTG TCG AGC ATC CAG CTT CAT GGC TGA GTC CAC AAT GZ. Z contain the modified nucleobase with an aminogroup, incorporated using the commercially available amino modifier C6 dT phosphoramidite (10-1039-90 from Glen research).

B) The middle chromatogram show the streptavidine purified amino oligo O after partial transfer of a functional entity (XXIII).

C) The bottom chromatogram show the streptavidine purified amino oligo O after the complete transfer of a more lipophilic functional entity (XVII). The following gradient was used: 0-3 minutes 100% A then 15% A and 85% B from 3-10 minutes.

[0807] The experiment where the template oligo was omitted showed no non-templated product formation. The results indicate that the efficiency of the templated synthesis was 80-100%. The reason for less than 100% efficiency was probably due to hydrolytic cleavage of the functional entity.

Example 106: General procedure for the templated synthesis of a scaffolded molecule where the scaffold and two identical substituents are encoded by the template

[0808]

[0809] The template oligo (1 nmol) was mixed with two thio oligos (K and L) loaded with the same functional entity (XXVI; 1 nmol) and the trisamine oligo H (1 nmol) in hepes-buffer (20 μ L of a 100 mM hepes and 1 M NaCl solution, pH=7.5) and water (added to a final volume of 100 μ L). The oligos were annealed to the template by heating to 50 $^{\circ}$ C and cooled (-2 $^{\circ}$ C/ 30 second) to 30 $^{\circ}$ C. The mixture was then left o/n at a fluctuating temperature (10 $^{\circ}$ C for 1 second then 35 $^{\circ}$ C for 1 second). The oligo complex was attached to streptavidine by addition of streptavidine beads (100 μ L, prewashed with 2x1 mL 100 mM hepes buffer and 1 M NaCl, pH=7.5). The beads were washed with hepes buffer (1 mL). The trisamine scaffold oligo H was separated from the streptavidine bound complex by addition of water (200 μ L) followed by heating to 70 $^{\circ}$ C. The water was transferred and evaporated *in vacuo*, resuspended in TEAA buffer (45 μ L of a 0.1 M solution) and product formation analysed by HPLC (see Figure 63).

[0810] The HPLC chromatogram shows the transfer of two functional entities to a scaffold oligo with three amino groups.

A) The top chromatogram shows the reference scaffold oligo G.

B) The bottom chromatogram show the streptavidine purified scaffold oligo G after the partial transfer of one (peak at 7.94 minutes) and two (peak at 10.76 minutes) identical functional entities (XXVI). The following gradient was used: 0-3 minutes 100% A then 15% A and 85% B from 3-10 minutes then 100% B from 10-15 minutes. A = 2% acetonitrile in 10 mM TEAA and B = 80% acetonitrile in 10 mM TEAA.

[0811] Due to the lipophilic nature of the functional entities a longer retention time, in the HPLC chromatogram, of the scaffolded molecule with two functional entities compared to one functional entity, was observed. The efficiency of the templated synthesis of a scaffolded molecule with the two identical functional entities (XXVI) was about 25% (peak at 10.76 minutes in Figure 63).

Example 107: Procedure for the templated synthesis of a scaffolded molecule, where the scaffold and the three substituents are encoded by the template

[0812]

[0813] Procedure A (5-mer zipper box): The template oligo (1 nmol) was mixed with three thio oligos (J-L) loaded with three different functional entity (XVI, XVII and XVIII, respectively; 1 nmol) and the trisamine scaffold oligo H (1 nmol) in

hepes-buffer (20 μ L of a 100 mM hepes and 1 M NaCl solution, pH=7.5) and water (added to a final volume of 100 μ L). The oligos were annealed to the template by heating to 50 $^{\circ}$ C and cooled (-2 $^{\circ}$ C/ 30 second) to 30 $^{\circ}$ C. The mixture was then left o/n at a fluctuating temperature (10 $^{\circ}$ C for 1 second then 35 $^{\circ}$ C for 1 second). The oligo complex was attached to streptavidine by addition of streptavidine beads (100 μ L, prewashed with 2x1 mL 100 mM hepes buffer and 1M NaCl, pH=7.5). The beads were washed with hepes buffer (1mL). The trisamine scaffold oligo was separated from the streptavidine bound complex by addition of water (200 μ L) followed by heating to 70 $^{\circ}$ C. The water was transferred and evaporated *in vacuo*, resuspended in TEAA buffer (45 μ L of a 0.1 M solution) and formation of the encoded molecule was identified by HPLC.

[0814] Procedure B (9-mer zipper box): The template oligo (15 pmol) was mixed with three methylamino oligos (C-E) loaded with three different functional entity (XXVII, XXIX and 4-acetoxybenzaldehyde, respectively; 20 pmol) and a P³² end labelled trisamine scaffold oligo I (15 pmol) in hepes-buffer (6.5 μ L of a 100 mM hepes and 1 M NaCl solution, pH=7.5). The mixture was heated to 58.5 $^{\circ}$ C and left at 58.5 $^{\circ}$ C for 5 days. Formation of the encoded molecule was identified by PAGE.

Example 108 (Model): Description of the preparation of a 3-mer β -amino acid library

A) Synthesis of the β -amino acid building blocks

[0815] N-terminal protection: The Nvoc group¹ (3,6-dimethoxy-6-nitrobenzyloxycarbonyl) was used as a photo cleavable N-protecting group and introduced on a β -amino acid according to the following method:

¹Burgess et al. J. Org. Chem. (1997), 62, 5165-68, Alvarez et al. J. Org. Chem. (1999), 64, 6319-28 and Pedersen et al. Proc. Natl. Acad. Sci. (1998), 95, 10523-28

[0816] 3-Amino-butanoic acid (147 mg, 1.43 mmol) was mixed with water (10 mL), dioxane (10 mL) and 2 M NaOH (10 mL). The mixture was cooled to 0 $^{\circ}$ C and treated with Nvoc-Cl (1.58 mmol). 2 M NaOH was added in small portions (8 x 1.25 mL) during 75 minutes. The cooling bath was removed and the reaction mixture was left at room temperature o/n. Water (30 mL) was added and the mixture was filtered. The aqueous phase was adjusted to pH = 4 with 2 M HCl (aq.) and extracted with diethyl ether (3 x 50 mL). The solid was dissolved in water (50 mL) and diethyl ether (50 mL). The combined organic phases were dried over MgSO₄ and evaporated *in vacuo* affording 176 mg (36 %) pure 3-(4,5-dimethoxy-2-nitrobenzyloxycarbonylamino)-butanoic acid. ¹H-NMR (CDCl₃): 7.72 (s, 1H), 7.02 (s, 1H), 5.51 (s, 2H), 5.40-5.30 (br s, 1H), 4.15 (m, 1H), 3.96 (s, 3H), 3.92 (s, 3H), 2.60 (d, 2H), 1.31 (d, 3H).

[0817] β -Alanin, cis-2-amino-1-cyclohexanecarboxylic acid, trans-2-Amino-1-cyclohexane carboxylic acid, cis-2-amino-1-cyclopentanecarboxylic acid, cis-2-amino-4-cyclohexene-1-carboxylic acid, trans-2-amino-4-cyclohexene-1-carboxylic acid, 3-amino-4,4,4-trifluoro butanoic acid, 3-amino-4-methylpentanoic acid, DL-3-aminoisobutyric acid monohydrate, 3-amino-3-phenylpropionic acid, 2-fluoro-3-aminopropionic acid hydrochloride are protected similarly.

[0818] C-terminal activation: The NHM (N-hydroxymaleimide) ester of the N-Nvoc protected β -amino acid was used and prepared according to the following method, exemplified using 3-(4,5-dimethoxy-2-nitro-benzyloxycarbonylamino)-3-phenyl-propionic acid:

[0819] 3-(4,5-dimethoxy-2-nitro-benzyloxycarbonylamino)-butanoic acid (418 mg, 1.22 mmol) was dissolved in THF (10

mL), N-hydroxymaleimide (1.22 mmol) was added and the mixture was cooled to 0 °C. Dicyclohexylcarbodiimide (1.22 mmol) was added and the reaction mixture was left o/n at room temperature. The solvent was removed by evaporation *in vacuo* and the product isolated by silica column purification using EtOAc-heptane (1:4 then 1:2 then 1:1) as eluent. Yield 219 mg (42 %) of pure 3-(4,5-dimethoxy-2-nitro-benzyloxycarbonylamino)-butyric acid 2,5-dioxo-2,5-dihydropyrrol-1-yl ester. ¹H-NMR (CDCl₃): 7.73 (s, 1H), 7.03 (s, 1H), 6.81 (s, 2H), 5.55 (dd, 2H), 5.30-5.20 (br s, 1 H), 4.25 (m, 1H), 3.98 (s, 3H), 3.97 (s, 3H), 2.86 (m, 2H), 1.39 (d, 3H).

[0820] The N-Nvoc protected analogues of β-Alanine, cis-2-amino-1-cyclohexanecarboxylic acid, trans-2-Amino-1-cyclohexanecarboxylic acid, cis-2-amino-1-cyclopentanecarboxylic acid, cis-2-amino-4-cyclohexene-1-carboxylic acid, trans-2-amino-4-cyclohexene-1-carboxylic acid, 3-amino-4,4,4-trifluorobutyric acid, 3-amino-4-methylpentanoic acid, DL-3-aminoisobutyric acid monohydrate, 3-amino-3-phenylpropionic acid, 2-fluoro-3-aminopropionic acid hydrochloride, are activated similarly.

B) Preparation of building block oligos:

[0821]

[0822] A thio oligo (1 nmol) is treated with 3-(4,5-dimethoxy-2-nitrobenzyloxycarbonylamino)-3-phenyl-propionic acid 2,5-dioxo-2,5-dihydro-pyrrol-1-yl ester (50 uL of 0.1 M solution in DMF). The mixture is left o/n at room temperature. The building block oligo is spun down (20.000 G for 15 minutes) and the DMF is removed. DMF (1 mL) is added, the building block oligo is spun down (20.000 G for 15 minutes) and the DMF is removed.

[0823] The N-Nvoc protected C-terminal NHM activated analogues of β-Alanine, cis-2-amino-1-cyclohexanecarboxylic acid, trans-2-Amino-1-cyclohexanecarboxylic acid, cis-2-amino-1-cyclopentanecarboxylic acid, cis-2-amino-4-cyclohexene-1-carboxylic acid, trans-2-amino-4-cyclohexene-1-carboxylic acid, 3-amino-4,4,4-trifluorobutyric acid, 3-amino-4-methylpentanoic acid, DL-3-aminoisobutyric acid monohydrate, DL-beta-aminobutyric acid, 2-fluoro-3-aminopropionic acid hydrochloride, are loaded on 11 different thio oligos similarly.

[0824] In the following any four of the prepared building block oligos are selected and used for library production.

[0827] 64 template oligos (2 pmol each) consisting of 3 coding regions are mixed with four different building block oligos (1-4, 200 pmol each) and hepes buffer (20 μ L, 100 mM hepes buffer and 1 M NaCl, pH = 7.5). Water is added to a final volume of 1000 μ L. The oligos are annealed to the templates by heating to 50 °C and cooled (-2 °C/ 30 second) to 20 °C. The Nvoc-protecting groups are removed by degassing thoroughly with Ar, followed by exposure to a mercury lamp (450 W HPLC mercury lamp, pyrex filter, cutoff<300 nm) for 1-2 hours. The mixture is left o/n at a fluctuating temperature (10 °C for 1 second then 35 °C for 1 second).

[0828] Formation of the encoded molecules in the library production is addressed in two separate experiments, where only one template is used in each experiment. The first template (3'-CGT ATG TTG ATA CAT AAT AAC GTA TGT TGA TAC ATA ATA ACG TAT GTT GAT ACA T) encode for the formation the 3-mer β -peptide of β -alanin and the other template (3'-CGT ATG CCG ATA CAT AAT AAC GTA TGC CGA TAC ATA ATA ACG TAT GCC GAT ACA T) for the formation of 3-mer β -peptide of 3-amino-4,4,4-trifluorobutyric acid.

[0829] A template oligo (2 pmol) consisting of 3 coding regions are mixed with four different building block oligos (1-4, 200 pmol each) and hepes buffer (20 μ L, 100 mM hepes buffer and 1 M NaCl, pH = 7.5). Water is added to a final volume of 100 μ L. The oligos are annealed to the templates by heating to 50 °C and cooled (-2 °C/30 second) to 20 °C. The Nvoc-protecting groups are removed by degassing thoroughly with Ar, followed by exposure to a mercury lamp (450 W HPLC mercury lamp, pyrex filter, cutoff<300 nm) for 1-2 hours. The mixture is left o/n at a fluctuating temperature (10 °C for 1 second then 35 °C for 1 second). The oligo complex is attached to streptavidine by addition of streptavidine beads (100 μ L, prewashed with 2x1 mL 100 mM hepes buffer and 1 M NaCl, pH=7.5). The beads are washed with hepes buffer (1mL). The building block oligo, containing the encoded product, is separated from the streptavidine bound complex by addition of water (200 μ L) followed by heating to 70 °C. The water is transferred and product formation verified by MS analysis.

Example 109 (Model): Description of the preparation of a 3-mer β -amino acid libraryA) Synthesis of the β -amino acid building blocks

[0830] N-terminal protection: The Nvoc group (3,6-dimethoxy-6-nitrobenzyloxycarbonyl) was used as a photo cleavable *N*-protecting group and introduced on a β -amino acid according to the method described above.

[0831] C-terminal activation: The N-Nvoc protected β -amino acid was activated using the known 1-(4-hydroxy-phenyl)-pyrrole-2,5-dione (Choi et al. Mol.Cryst.Liq.Cryst.Sci. Technol.Sect.A (1996), 280, 17-26), according to the following method:

[0832] 1-(4-Hydroxy-phenyl)-pyrrole-2,5-dione (1 mmol), NHS (1.0 mmol) and 3-(4,5-dimethoxy-2-nitro-benzyloxycarbonylamino)-butyric acid (1 mmol) is dissolved in THF (3 mL). The solution is cooled to 0 °C and treated dropwise with DIC (1.2 mmol). The cooling bath is removed after 1 hour and the reaction mixture is left at room temperature o/n. The solvent is evaporated *in vacuo* and the pure product (3-(4,5-dimethoxy-2-nitro benzyloxycarbonyl-amino)-butyric acid 4-(2,5-dioxo-2,5-dihydro-pyrrol-1-yl)-phenyl ester) is isolated by silica column purification using EtOAc-heptane (1:4 then 1:2 then 1:1) as eluent.

[0833] The *N*-Nvoc protected analogues of β -Alanin, *cis*-2-amino-1-cyclohexanecarboxylic acid, *trans*-2-Amino-1-cyclohexanecarboxylic acid, *cis*-2-amino-1-cyclopentanecarboxylic acid, *cis*-2-amino-4-cyclohexene-1-carboxylic acid, *trans*-2-amino-4-cyclohexene-1-carboxylic acid, 3-amino-4,4,4-trifluorobutyric acid, 3-amino-4-methylpentanoic acid, DL-3-aminoisobutyric acid monohydrate, DL-beta-aminobutyric acid, 2-fluoro-3-aminopropionic acid hydrochloride, are C-terminal activated similarly.

B) Preparation of building block oligos:

[0834]

[0835] A thio oligo (2 nmol) in water (25 μ L) is treated with 3-(4,5-dimethoxy-2-nitrobenzyloxycarbonyl-amino)-butyric acid 4-(2,5-dioxo-2,5-dihydro-pyrrol-1-yl)-phenyl ester (25 μ L of a 10 mM solution in MeOH). The mixture is left o/n at room temperature. The building block oligo is purified by a conventional EtOH-precipitation. The pellet is washed with dichloromethane (3 x 300 μ L) and dried *in vacuo*.

[0836] The *N*-Nvoc protected C-terminal activated analogues of β -Alanin, *cis*-2-amino-1-cyclohexane-carboxylic acid,

trans-2-Amino-1-cyclohexanecarboxylic acid, cis-2-amino-1-cyclopentane-carboxylic acid, cis-2-amino-4-cyclohexene-1-carboxylic acid, trans-2-amino-4-cyclohexene-1-carboxylic acid, 3-amino-4,4,4-trifluorobutyric acid, 3-amino-4-methylpentanoic acid, DL-3-aminoisobutyric acid monohydrate, DL-betaaminobutyric acid, 2-fluoro-3-aminopropionic acid hydrochloride, are loaded on 11 different thio oligos similarly.

[0837] Any four of the prepared building block oligos are selected and used for library production as described above.

Example 110 (Model): In the following, a library preparation method based on oligonucleotide templates and 5'-phosphoimidazolid nucleoside building blocks is described.

Preparation of building blocks

[0838]

Step A: Preparation of an ester linker with a terminal alkyne.

[0839] The acid derivative (10.37 mmol) is dissolved in DCM (20 mL) and cooled to 0 °C on an ice bath. EDC (12.44 mmol, 1.2 equiv) is added followed by DMAP (1.04 mmol, 0.1 equiv) and the alcohol (15.55 mmol, 1.5 equiv) in DCM (5 mL). After 1h reaction on ice bath, the mixture is allowed to come to 20 °C and left to react 16h. Volatiles are removed and the residue is taken up in diethylether (150 mL) and HCl (aq, 0.1 M, 75 mL). The phases are separated and the organic phase is first washed with a mixture of NaHCO₃ (sat, 35 mL) and water (35 mL) then with water (75 mL). Upon evaporation of diethylether, the product is azeotropically dried using toluene (2x120 mL) affording the desired ester that may be purified by chromatography if necessary.

Step B: Introduction of protective groups on iodo substituted nucleosides.

[0840] The nucleoside (5.65 mmol, 1 eq), TBDMS-Cl (2.04g, 13.56 mmol, 2.4 eq) and imidazole (1.85g, 27.11 mmol, 4.8 eq) are mixed in DMF (20 mL) and stirred at 25 °C overnight. EtOAc (400 mL) is added and the organic phase is washed with a mixture of NH₄Cl(aq) (sat, 40 mL) + H₂O (40 mL) followed by H₂O (80 mL). The organic phase is stripped and the residue is taken up in toluene, filtered and stripped to leave the desired protected nucleoside. The compound may be further purified by recrystallization.

Step C: Sonogashira coupling of protected iodo substituted nucleosides and terminal alkynes

[0841] A DMF solution (20 mL) of the protected iodo substituted nucleoside (3.4 mmol), the alkyne (6.9 mmol, 2 eq), DIEA (2.5 mL) is purged with Ar for 5 min. Tetrakis triphenylphosphine palladium (0.3 mmol, 0.1 eq) and CuI (0.7 mmol, 0.2 eq) is added and the mixture is heated to 50 °C and kept there for 20 h. Upon cooling, the mixture is added 700 mL diethylether. The organic phase is washed with ammonium chloride (sat, aq, 250 mL) and water (250 mL). Evaporation of volatiles followed by stripping with toluene (400 mL) affords the desired modified nucleoside that is purified by column chromatography (silica gel, Heptane/Ethyl acetate eluent).

Step D: Removal of OH protective groups

[0842] A THF solution of the above product (1.8 mmol in 30 mL) is added acetic acid (0.8 mL, 14.1 mmol, 8 eq) and tetrabutylammonium fluoride (7 mmol, 4 eq). Upon stirring at 20 °C for 20 h, volatiles are removed *in vacuo* and the residue is purified by column chromatography (silica gel, DCM/Methanol eluent).

Step E: Mono-phosphate synthesis

[0843] A slurry of the modified nucleoside obtained in step D (1.65 mmol) in trimethyl phosphate (5 mL) is cooled to 0 °C and added phosphoroyl trichloride (190 uL, 307 mg, 2 mmol, 1.2 eq). The reaction is kept at 0 °C for 2h. Tributyl amine (1 mL) is added and the reaction is allowed to come to 20 °C. Another portion of tributyl amine (1.3 mL) is added to raise pH, followed by water. Volatiles are removed *in vacuo* and the residue may be purified using ion-exchange chromatography (Sephadex A25, tetraethylammonium bromide buffer 0.05-1.0 M, pH 7).

Step F: Phosphoimidazolid synthesis

[0844] To a solution of the above mono-phosphate derivative (0.1 M) is added 2-methylimidazole (0.5 M) and EDC (0.5 M) at pH 6.5 and 0 °C. The reaction is stirred for 2h maintaining a temperature of 0 °C. The mixture may be used directly in library synthesis. [Visscher;1988; Journal of Molecular Evolution; 3-6]
Alternatively, treatment of phosphates with carbonyl diimidazole also affords phosphoimidazolidines. [Zhao;1998; J. Org. Chem.; 7568-7572]

A collection of building blocks

[0845] In the the scheme below a number of building blocks useful for library synthesis is shown. All building blocks have functional entities attached to the recognition element by means of an carboxylic ester and may be synthesized

as described above.

Library preparation

[0846] The scheme below exemplifies the process of making a library of polyamides using oligonucleotide templates and phosphoimidazolid building blocks shown above. An oligonucleotide primer sequence with a sequence modifier carrying an (optionally) protected amine (e.g. Glen Research Amino-Modifier C2 dT, cat no 10-1019-) is annealed to the templates used in the library. Further, another oligonucleotide sequence is annealed as a terminating sequence thus exposing only the part of the template coding the building block incorporation. For clarity, the bases of the phosphoimidazolid building blocks have been replaced with large bold letter codes.

Incorporation

[0847] Typical conditions for oligomerisation of building blocks on the template are 0.05 M templates, 0.1-0.2 M building blocks, in a 0.2 M 2,6-lutidine-HCl buffer adjusted to pH = 7.2 buffer containing 1.0 M sodium chloride 0.2 M magnesium chloride. The temperature is kept at 0 °C for 1-21 days. [Inoue;1984; Journal of Molecular Biology, 669-676] . The oligonucleotide complexes may be purified using micro-spin gel filtration (BioRad).

Amine deprotection

[0848] Cbz protection groups may be removed by a variety of methods, [Greene;1999;] Due to its mildness, catalytic reduction is often the method of choice. Combining an insoluble hydrogenation catalyst e.g. Pd/Al₂O₃, Pd/CaCO₃, Pd/C, PtO₂, or a soluble one e.g. Wilkinsons catalyst and a hydrogen source exemplified but not limited to H₂, ammonium formate, formic acid, 1,4-cyclohexadien, and cyclohexene in a suitable solvent like water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylen glycol, acetonitril, acetic acid or a mixture of these with the oligo nucleotide complexes removes the Cbz protective groups.

Polymerisation

[0849] Di-amines are linked together using di-carboxylic acids, a peptide coupling reagent optionally in the presence of a peptide coupling modifier in a suitable solvent like water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile or a mixture of these. To an aqueous buffered solution (10uL, 1 M NaCl, 100-500 mM buffer pH 6-10, preferably 7-9) of oligonucleotide complexes (0.1-100 uM, preferably 0.5-10 uM) carrying free di-amines is added a di-carboxylic acid (0.1mM-100mM, preferably 1-10 mM) exemplified by but not limited to oxalic-, malonic-, succinic-, pentanedioic- or hexanedioic acid, phthalic-, isophthalic, terephthalic acid, N-protected glutamic acid or N-protected aspartic acid mixed with a peptide coupling reagent (0.1 mM - 100 mM, preferably 1-10 mM) exemplified by but not limited to EDC, DCC, DIC, HATU, HBTU, PyBoP, PyBroP or N-methyl-2-chloropyridinium tetrafluoroborate and a peptide coupling modifier (0.1 mM-100 mM, preferably 1-10 mM) exemplified by but not limited to NHS, sulpho-NHS, HOBt, HOAt, DhbtOH in a suitable solvent (1uL) e.g. water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile or a mixture of these.

[0850] Reactions run at temperatures between -20°C and 100°C, preferably between 0 °C and 60°C. Reaction times are between 1 h and 1 week, preferably 1 h-24h. The above procedure exemplifies the polymerisation on a 11 uL scale, but any other reaction volume between 1.1 uL and 1.1L may be employed.

Linker cleavage

[0851] The ester linkages are cleaved with aqueous hydroxide at pH 9-12 at room temperature, 16 h in a suitable solvent like water, methanol, ethanol, dimethylformamide, dimethylsulfoxide, ethylene glycol, acetonitrile or a mixture of these.

MS-Analysis

[0852] Library members may be analyzed using Mass Spectroscopy.

[0853] In the above sequence, diamines carry Cbz protection groups and are deprotected on the oligonucleotide. Other protection schemes may also be relevant for amine protection. [Greene and Wuts;1999;] In some cases it may suffice running the sequence with building blocks that do not carry protective groups on the amines, hence eliminating the amine deprotection step. The described procedure for templated library synthesis may also employ the use of modified di- and tri-nucleotides as well as modified nucleic acid analogues like morpholinos, LNA and PNA. In the latter case reaction conditions during incorporation should be changed to accommodate peptide coupling reactions. [Schmidt; 1997; Nucleic Acids Research; 4792-4796] Examples of such alternative building blocks are shown in the scheme below. Synthesis of the modified PNA units compared to ordinary PNA units differs only in the use of modified bases.

Modified di-nucleotide**Modified di-PNA**

[0854] Further, instead of using 5'-phosphoimidazolidine-nucleosides, a mixture of bis-3',5' phosphoimidazolidine-nucleosides [Vischer and Schwartz; 1988; Journal of Molecular Evolution; 3-6] and nucleosides may be employed in library production, see below. Alternating incorporation of each building block type is required, but due to the reversibility of the recognition step and the fact that no reaction takes place if for instance two bis-3',5' phosphoimidazolidine-nucleosides are placed next to each other all that is necessary is that both building block types are present in the mixture.

Example 111 (Model): Synthesis of a library of templated molecules by non-enzymatic ligation of dinucleotides comprising functional entities.

[0856] Several systems have been developed that enable the non-enzymatic chemical ligation of nucleotides and oligonucleotides on nucleic acid or PNA templates (Xu et al., 2001, *Nat Biotechnol* 19, 148-152; 2000, *J Am Chem Soc*, 122, 9040-41). One protocol describes the autoligation of 3'-phosphothioate and a 5' moiety comprising an iodine leaving group as shown below.

[0857] The non-enzymatic ligation protocol can be used for the templated synthesis of a library of molecules. Here, a set of dinucleotides each comprising a unique functional entity was synthesised by modified phosphoramidite nucleotide chemistry as described below. 4 di-nucleotide building blocks with the sequences dUdNp were synthesised. Each di-nucleotide comprises a 5'-iodo- and a 3'-phosphothioate group capable of forming a covalent bond with a neighbouring reactive group.

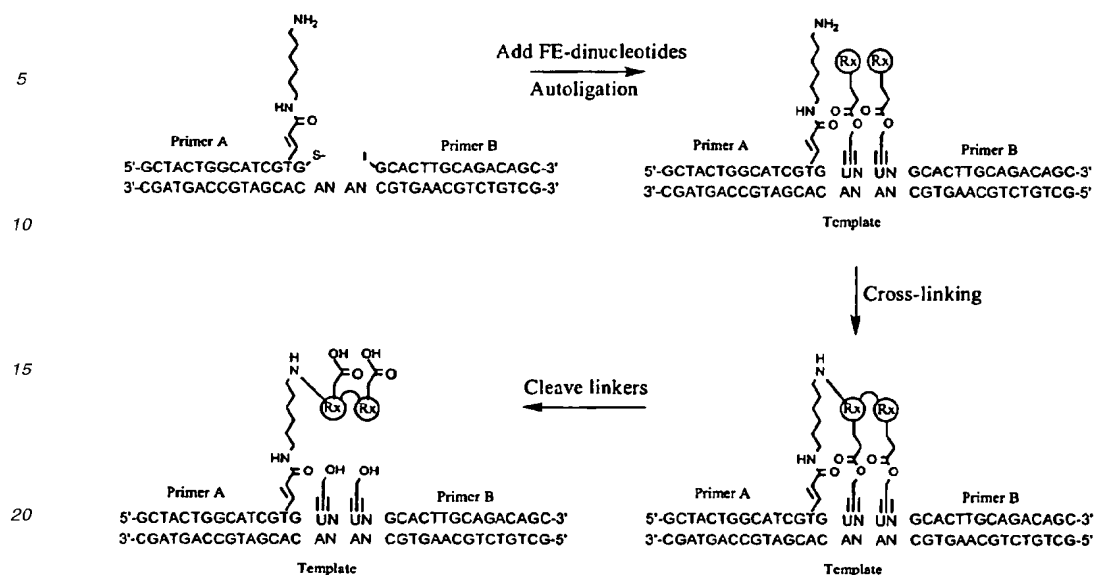

Incorporation of di-nucleotides on a DNA template:

[0858] 1 pmol each of extension primers A (5'-GCTACTGGCATCGXG-3'-phosphothioate, where X denotes deoxythymidine-C6-NH₂, Glen Research Cat#: 10-1035-90) and B (5'-iodo-GCACTTGCAGACAGC-3') are annealed to a template oligo (5'-GCTGTCTGCAAGTGCNANACACGATGCCAGTAGC-3') in a binding buffer: 50 mM HEPES-KOH, pH=7.5, 5 mM MgCl₂, 100 mM KCl and incubated at 80 °C for 2 minutes before slowly cooling down to 20 °C. The binding of primer A and B to the template forms a double stranded DNA complex with a central 4 nucleotide single-stranded segment as shown below. 10 pmol of di-nucleotides are added and the reaction mixture is incubated at 4 °C for 30 min followed by a brief heating to 25 °C for 30 seconds. The reaction mixture is subjected to successive temperature oscillation cycles for 24 hours. This step promotes the chemical ligation between correctly annealed dinucleotides and the primers A and B.

[0859] Following template complementation and chemical ligation, dinucleotides and buffer are removed by micro-spin gelfiltration (Biorad).

Cross-linking of functional entities and activation of templated molecules.

[0860] The DNA complexes comprising the functional entities are incubated in a buffer 20 mM HEPES-KOH pH = 7.5, 100 mM KCl. 5 mM Bis[Sulfosuccinimidyl]suberate (BS₃, Pierce) is added and the sample is incubated at 30 °C for 2-8 hours. Buffer and excess BS₃ are removed by micro-spin gelfiltration (Biorad). The templated molecules are activated by cleavage of the ester linkages using 0.2 M NaOH at 50 °C for 15 min before addition of equimolar HCl. The sample is transferred to a suitable buffer by dialysis.

[0861] This protocol allows for the synthesis of a small library of 16 different molecules each linked to their template applicable for selection/amplification experiments. Larger libraries can be synthesised using tri-, tetra-, or other oligonucleotides comprising functional entities and/or by increasing the number of building blocks to be coupled by non-enzymatic ligation on the DNA template.

Synthesis of building blocks:

[0862] Synthesis of 5'-iodo-3'-phosphonothioate dimers with a functional entity attached

a) Conventional phosphoramidite coupling; b) S₈ in pyridine; c) phosphoramidite coupling to introduce 5-I-dU; d) CF₃COOH then I₂/pyridine/water; e) FE-spacer and Pd(O) in THF-Et₃N; f) Ph₃P and I₂ in DMF; g) photolysis >300 nm.

[0863] B equals either A, T, G or C properly protected with the photolabile protecting group Nvoc². Linker equals a photolabile CPG solid support.³ R equals a photolabile phosphate protecting group.⁴

Example 112: Ligation of DNA oligonucleotides, derivatized at the central nucleotide.

[0866] In order to examine the substrate efficiency of various DNA oligo-derivatives for T4 DNA ligase, oligo-derivatives Ah17 and Ah19 and were annealed to templates Ah18 and Ah20, respectively. Each of the templates contain two annealing sites for the appropriate oligo. The oligo-derivatives contain a modified nucleotide at the central nucleotide position (see figure below).

[0867] The reaction may be schematically represented as indicated below:

X= Amino-Modifier C6 dT

Ah 17: 5'- CACXGAA

Ah 18: 5'- TCGGATTCAGTGTTTCAGTGCGTAG

Ah 19: 5'- TGCACXGAAGC

Ah20: 5'- TCGGAGCTTCAGTGCAGCTTCAGTGCACGTAG

[0868] Mix 0,5 µl buffer A, 0,5µl Ah18 or Ah20 (1 pmol/µl), and 2 µl Ah17 or Ah18 (³²P-labelled) (1 pmol/µl). Anneal by heating to 80°C and then cool to 10°C. Add 3 µl T4-DNA Ligase (TAKARA, code #6022). Incubate at 4,7°C for about 48h. Then analyze by 10% urea polyacrylamide gel electrophoresis.

[0869] As seen in figure 64, the DNA ligase is able to efficiently ligate both oligo-derivatives tested, i.e. even for the shortest oligo (Ah17), with a length of 7 nucleotides, and a modification at position 4, ligation goes to approximately 50% completion.

Claims

30

1. A method for synthesising a composition of different templated molecules comprising a plurality of functional groups, said method comprising the steps of

i) providing a plurality of templates having different coding elements and/or a different order of coding elements, said templates comprising a plurality of nucleotides and a sequence of n coding elements, wherein each coding element comprises at least one recognition group capable of recognising a predetermined complementing element, and wherein n is an integer of more than 1,
 ii) providing a plurality of building blocks, wherein each building block comprises

35

a) at least one complementing element comprising at least one recognition group capable of recognising a predetermined coding element,
 b) at least one functional entity comprising at least one functional group and at least one reactive group, and
 c) at least one linker separating the at least one functional entity from the at least one complementing element,

40

iii) contacting each of said coding elements with a complementing element capable of recognising said coding element said complementing element comprising a plurality of nucleotides,
 iv) obtaining a complementing template by linking enzymatically the complementing elements, and
 v) obtaining a composition of different templated molecules each comprising covalently linked, functional groups by linking a functional group of at least one functional entity to a functional group of another functional entity,

45

wherein the templated molecule is linked by means of a linker to the complementing template or template that templated the synthesis of the templated molecule, and
 wherein the synthesis of the templated molecules does not involve ribosome mediated translation of a nucleic acid.

55

2. Method of claim 1, wherein the templated molecule is linked by means of a single linker to the complementing template or template that templated the synthesis of the templated molecule.

3. The method of claim 1, wherein steps iii) through v) are repeated for different building blocks.

4. The method of claim 1, wherein the n coding elements form a linear sequence.

5 5. The method of claim 1, wherein the template comprising n coding elements is branched.

6. The method of claim 1, wherein n has a value of from 2 to 200.

7. The method of claim 1, wherein n has a value of from 2 to 100.

10 8. The method of claim 1, wherein n has a value of from 2 to 20.

9. The method of claim 1, wherein n has a value of from 2 to 10.

15 10. The method of claim 1, wherein n has a value of from 3 to 100.

11. The method of claim 1, wherein n has a value of from 3 to 20.

12. The method of claim 1, wherein n has a value of from 3 to 10.

20 13. The method of claim 1, wherein n has a value of from 3 to 8.

14. The method of claim 1, wherein n has a value of from 3 to 6.

25 15. The method of claim 1, wherein n has a value of from 4 to 20.

16. The method of claim 1, wherein n has a value of from 4 to 10.

17. The method of claim 1, wherein n has a value of from 4 to 8.

30 18. The method of claim 1, wherein n has a value of from 4 to 6.

19. The method of claim 1, wherein n has a value of from 5 to 10.

35 20. The method of claim 1, wherein n has a value of from 5 to 8.

21. The method of claim 1, wherein n has a value of from 6 to 10.

22. The method of claim 1, wherein n has a value of from 6 to 8.

40 23. The method of claim 1, wherein the template is attached to a solid support

24. The method of claim 1, wherein the template comprises or consists of nucleotides selected from the group consisting of deoxyribonucleic acids (DNA), ribonucleic acids (RNA), peptide nucleic acids (PNA), locked nucleic acids (LNA), and morpholino sequences.

45 25. The method of claim 1, wherein the template comprises or essentially consists of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholinos sequence, and wherein the complementing element comprises or essentially consists of nucleotides selected from the group consisting of DNA, RNA, PNA, LNA and morpholino sequences.

50 26. The method of claim 1, wherein the template is amplifiable.

55 27. The method of claim 26, wherein a single strand of template coding elements forms a double helix by hybridization to a complementing template comprising a single strand of complementing elements.

28. The method of any of claims 1 to 27, wherein the template comprises a priming site.

29. The method of claim 1, wherein the coding elements comprise or consist of from 2 to 100 subunits.
30. The method of claim 1, wherein the coding elements comprise or consist of from 3 to 40 subunits.
- 5 31. The method of claim 1, wherein the coding elements comprise or consist of from 3 to 20 subunits.
32. The method of claim 1, wherein the coding elements comprise or consist of from 4 to 40 subunits.
33. The method of claim 1, wherein the coding elements comprise or consist of from 4 to 20 subunits.
- 10 34. The method of claim 1, wherein the coding elements comprise or consist of from 5 to 40 subunits.
35. The method of claim 1, wherein the coding elements comprise or consist of from 5 to 20 subunits.
- 15 36. The method of claim 1, wherein the coding elements comprise or consist of from 6 to 40 subunits.
37. The method of claim 1, wherein the coding elements comprise or consist of from 6 to 20 subunits.
38. The method of claim 1, wherein the coding elements comprise or consist of from 8 to 40 subunits.
- 20 39. The method of claim 1, wherein the coding elements comprise or consist of from 8 to 20 subunits.
40. The method of claim 1, wherein the coding elements comprise or consist of from 10 to 40 subunits.
- 25 41. The method of claim 1, wherein the coding elements comprise or consist of from 10 to 20 subunits.
42. The method of claim 1, wherein the coding elements comprise or consist of from 12 to 40 subunits.
43. The method of claim 1, wherein the coding elements comprise or consist of from 12 to 20 subunits.
- 30 44. The method of claim 1, wherein the coding elements comprise or consist of from 14 to 40 subunits.
45. The method of claim 1, wherein the coding elements comprise or consist of from 14 to 20 subunits.
- 35 46. The method of claim 1, wherein the coding elements comprise or consist of from 16 to 40 subunits.
47. The method of claim 1, wherein the coding elements comprise or consist of from 18 to 40 subunits.
48. The method of claim 1, wherein the coding elements comprise or consist of from 20 to 40 subunits.
- 40 49. The method of any of claims 29 to 48, wherein each subunit comprises or consists of a nucleotide.
50. The method of claim 1, wherein the complementing template comprising n complementing elements is a linear sequence of complementing elements.
- 45 51. The method of claim 1, wherein the complementing template comprising n complementing elements is branched.
52. The method of any of claims 50 and 51, wherein n has a value of from 2 to 100.
- 50 53. The method of any of claims 50 and 51, wherein n has a value of from 4 to 40.
54. The method of any of claims 50 and 51, wherein n has a value of from 4 to 20.
55. The method of any of claims 50 and 51, wherein n has a value of from 8 to 40.
- 55 56. The method of any of claims 50 and 51, wherein n has a value of from 8 to 20.
57. The method of any of claims 50 and 51, wherein n has a value of from 10 to 40.

58. The method of any of claims 50 and 51, wherein n has a value of from 10 to 20.
59. The method of any of claims 50 and 51, wherein n has a value of from 12 to 40.
- 5 60. The method of any of claims 50 and 51, wherein n has a value of from 14 to 40.
61. The method of any of claims 50 and 51, wherein n has a value of from 16 to 40.
62. The method of any of claims 50 and 51, wherein n has a value of from 18 to 40.
- 10 63. The method of any of claims 50 and 51, wherein n has a value of from 20 to 40.
64. The method of claim 1, wherein the complementing template is attached to a solid support.
- 15 65. The method of claim 1, wherein the complementing elements are selected from the group consisting of nucleotides.
66. The method of claim 1, wherein the complementing elements preferably comprise or consist of from 2 to 100 subunits.
67. The method of claim 1, wherein the complementing elements preferably comprise or consist of from 4 to 40 subunits.
- 20 68. The method of claim 1, wherein the complementing elements preferably comprise or consist of from 4 to 20 subunits.
69. The method of claim 1, wherein the complementing elements preferably comprise or consist of from 6 to 40 subunits.
- 25 70. The method of claim 1, wherein the complementing elements preferably comprise or consist of from 6 to 20 subunits.
71. The method of claim 1, wherein the complementing elements preferably comprise or consist of from 8 to 40 subunits.
72. The method of claim 1, wherein the complementing elements preferably comprise or consist of from 8 to 20 subunits.
- 30 73. The method of any of claims 66 to 72, wherein each subunit comprises or consists of a nucleotide.
74. The method of claim 1, wherein the complementing elements are selected from oligonucleotides and the complementing elements are linked enzymatically using a ligase.
- 35 75. The method of claim 74, wherein the complementing element oligonucleotides each comprise three or more nucleotides.
- 40 76. The method of claim 75, wherein the complementing element oligonucleotides each comprise from 4 to 100 nucleotides.
77. The method of claim 1, wherein two linkers of distinct building blocks each comprises a nucleotide sequence capable of forming a dimerisation domain by reversible interaction of the nucleotide sequences.
- 45 78. The method of any of the claims 1 to 77, wherein the templated molecule is a linear sequence of functional groups.
79. The method of any of the claims 1 to 77, wherein the templated molecule is a branched sequence of functional groups.
80. The method of any of the claims 1 to 77, wherein the templated molecule is a cyclic sequence of functional groups.
- 50 81. The method of claim 1, wherein the templated molecule comprises or consists of molecular entities selected from the group of α -peptides, β -peptides, γ -peptides, ω -peptides, mono-, di- and tri-substituted α -peptides, β -peptides, γ -peptides, ω -peptides, peptides wherein the amino acid residues are in the L-form or in the D-form, vinylogous polypeptides, glycopoly-peptides, polyamides, vinylogous sulfonamide peptide, polysulfonamide, conjugated peptides comprising e.g. prosthetic groups, polyesters, polysaccharides, polycarbamates, polycarbonates, polyureas, polypeptidylphosphonates, polyurethanes, azatides, oligo N-substituted glycines, polyethers, ethoxyformacetal oligomers, poly-thioethers, polyethylene glycols (PEG), polyethylenes, polydisulfides, polyarylene sulfides, polynucleotides, PNAs, LNAs, morpholinos, oligo pyrrolinone, polyoximes, polyimines, polyethyleneimines, polyimides,
- 55

polyacetals, polyacetates, polystyrenes, polyvinyl, lipids, phospholipids, glycolipids, polycyclic compounds comprising e.g. aliphatic or aromatic cycles, including polyheterocyclic compounds, proteoglycans, and polysiloxanes.

5 82. The method of claim 1, wherein neighbouring residues of the templated molecule is linked by a chemical bond selected from the group of chemical bonds consisting of peptide bonds, sulfonamide bonds, ester bonds, saccharide bonds, carbamate bonds, carbonate bonds, urea bonds, phosphonate bonds, urethane bonds, azatide bonds, peptoid bonds, ether bonds, ethoxy bonds, thioether bonds, single carbon bonds, double carbon bonds, triple carbon bonds, disulfide bonds, sulfide bonds, phosphodiester bonds, oxime bonds, imine bonds, imide bonds.

10 83. The method of claim 82, wherein the chemical bond linking functional entities of two or more building blocks is formed by a reaction of a nucleophile group of a first functional entity with an ester or thioester of another functional entity.

15 84. The method of claim 82, wherein the linker of the building block bearing the thioester group is cleaved simultaneously with the formation of the bonding resulting in a transfer of functional group to the nucleophilic building block.

85. The method of any of claims 83 and 84, wherein the nucleophile group is selected from -NH_2 , $\text{H}_2\text{NHN-}$, HOHN- , $\text{H}_2\text{N-C(O)-NH-}$.

20 86. The method of claim 1, wherein the backbone structure of said templated molecules comprise or consist of a molecular group selected from -NHN(R)CO- ; -NHB(R)CO- ; -NHC(RR')CO- ; -NHC(=CHR)CO- ; $\text{-NHCe H}_4\text{ CO-}$; $\text{-NHCH}_2\text{ CHR CO-}$; $\text{-NHCHRCH}_2\text{ CO-}$; $\text{-COCH}_2\text{-}$; -COS- ; -CONR- ; -COO- ; -CSNH- ; $\text{-CH}_2\text{ NH-}$; $\text{-CH}_2\text{CH}_2\text{-}$; $\text{-CH}_2\text{ S-}$; $\text{-CH}_2\text{ SO-}$; $\text{-CH}_2\text{SO}_2\text{-}$; $\text{-CH(CH}_3\text{) S-}$; -CH=CH- ; -NHCO- ; -NHCONH- ; -CONHO- ; $\text{-C(=CH}_2\text{)CH}_2\text{-}$; $\text{-PO}_2\text{-NH-}$; $\text{-PO}_2\text{-CH}_2\text{-}$; $\text{-PO}_2\text{-CH}_2\text{N}^+\text{-}$; $\text{-SO}_2\text{NH-}$; and lactams.

25 87. The method of claim 1, wherein a functional group at at least one functional entity is linked to another functional entity by means of a bridging molecule.

88. The method of claim 1, wherein the templated molecules comprise or consist of at least 2 different functional groups.

30 89. The method of claim 1, wherein the templated molecules comprise or consist of at least 3 different functional groups.

90. The method of claim 1, wherein the templated molecules comprise or consist of at least 4 different functional groups.

35 91. The method of claim 1, wherein the templated molecules comprise or consist of at least 5 different functional groups.

92. The method of claim 1, wherein the complementing element of each building block comprises at least one reactive group type I.

40 93. The method of claim 1, wherein the functional entity of each building block comprises at least one reactive group type II.

45 94. The method of claim 92, wherein the complementing element of each building block comprises two reactive groups type I.

95. The method of claim 93, wherein the functional entity of each building block comprises two reactive groups type II.

96. The method of claim 93, wherein the functional entity of at least one building block comprises three or four reactive groups type II.

50 97. The method of any of claims 95 and 96, wherein the reactive groups type II are reaction partners.

98. The method of claim 97, wherein the reactive groups type II are capable of forming a linkage between the functional groups through a bridging molecule.

55 99. The method of claim 98, wherein the bridging molecule is a di-functional compound with reactive groups which are reaction partners to the reactive groups type II of the functional entities.

100. The method of claim 95, wherein the reactive groups type II are different reaction partners.
101. The method of claim 100, wherein the different reactive groups type II are capable of forming a linkage between the functional groups through a bridging molecule.
102. The method of claim 101, wherein the bridging molecule is a di-functional compound with reactive groups which are reaction partners with the reactive groups type II of the functional entities.
103. The method of any of claims 95 to 102, wherein the at least one reactive group type II of the functional entity is selected from the group consisting of N-carboxyanhydride (NCA), N-thiocarboxyanhydride (NTA), coumarin, amine, carboxylic acid, ketone, aldehyde, hydroxyl, thiol, ester, thioester, alkenyl, any conjugated system of double bonds, hydrazine, N-hydroxysuccinimide ester, and epoxide.
104. The method of any of claims 95 to 102, wherein the reactive group type II is an electrophile.
105. The method of claim 104, wherein the reactive group type II is an electrophile selected from the group consisting of $-X-C(O)-R$, $-X-C(O)-CHRC(O)-R$, $-X-C(O)-CR=CH-R$, and $-X-C(O)-CHR-NHR$, wherein X is S or O, and R independently is a functional group.
106. The method of any of claims 95 to 102, wherein the reactive group type II is a nucleophile.
107. The method of claim 106, wherein the reactive group type II is a nucleophile selected from the group consisting of $-NH_2$, H_2NHN- , $HOHN-$, and $H_2N-C(O,S)-NH-$.
108. The method of claims 95 to 102, wherein the reactive group type II is a radical.
109. The method of any of the preceding claims, wherein a functional entity is restricted as to rotation to obtain a preferred orientation during formation of linkages to other functional entities.
110. The method of any of the preceding claims, wherein the formation of the templated molecule involves reactive groups type II capable of forming a polymer through anionic, cationic, or radical polymerisation.
111. The method of any of the preceding claims, comprising a scaffold functional entity comprising one of more reactive groups type II, said scaffold functional entity being the basic chemical structure for forming a templated molecule by addition of functional groups emanating from the plurality of building blocks.
112. The method of claim 111, wherein the scaffold functional entity comprises two or more reactive groups type II.
113. The method of any of claims 111 and 112, wherein the scaffold functional entity is linked covalently to the template.
114. The method of any of claims 111 and 112, wherein the scaffold functional entity is linked to a complementing element capable of recognising a coding element of the template.
115. The method of any of claims 111 to 114, wherein a scrambling of linking of functional groups to the scaffold functional entity is obtained by having a different number of reactive groups type II on the scaffold functional entity compared to the number of reactive groups type II on the functional entities of the plurality of building blocks.
116. The method of any of the claims 111 to 115, wherein the reaction of the reactive groups type II on the scaffold and the corresponding reactive groups type II on the building blocks result in a simultaneous linkage of the functional groups to the scaffold functional entity and cleavage of the linker connecting the functional entity with the complementing element.
117. The method of claim 1, wherein four or more different templates are used.
118. The method of claim 1, wherein more than 10^3 different templates are used.
119. The method of claim 1, wherein more than 10^5 different templates are used.

120. The method of claim 1, wherein more than 10^7 different templates are used.

121. The method of claim 1, wherein the plurality of different templates results in the formation of a library of different templated molecules, each of said templated molecules being connected to the specific template that templated the synthesis of said molecule.

122. The method of claim 1, wherein the plurality of different templates results in the formation of a library of different templated molecules, each of said templated molecules being connected to the specific complementing template that templated the synthesis of said molecule.

123. The method of any of the preceding claims comprising the further step of releasing the template or complementing template from the templated molecule, and obtaining a templated molecule that is not linked to the complementing template or template that templated the synthesis of the templated molecule.

124. A composition of different templated molecules, wherein each of said templated molecules is linked to the specific complementing template that templated the synthesis of the templated molecule, wherein the templated molecules are not alpha-peptides, and wherein the composition is obtained by the method of claim 122.

125. The composition according to claim 124, said composition comprising a plurality of about 10^3 different templated molecules.

126. The composition according to claim 124, said composition comprising a plurality of about 10^4 different templated molecules.

127. The composition according to claim 124, said composition comprising a plurality of about 10^5 different templated molecules.

128. The composition according to claim 124, said composition comprising a plurality of about 10^6 different templated molecules.

129. The composition according to claim 124, said composition comprising a plurality of about 10^7 different templated molecules.

130. The composition according to claim 124, said composition comprising a plurality of about 10^8 different templated molecules.

131. The composition according to claim 124, said composition comprising a plurality of about 10^9 different templated molecules.

132. The composition according to claim 124, said composition comprising a plurality of about 10^{10} different templated molecules.

133. The composition according to any of claims 124 to 132 further comprising the templates that templated the synthesis of the different templated molecules, or a subset thereof.

134. The composition according to claim 133, wherein the templated molecule is covalently linked to the template that templated the synthesis of the templated molecule.

135. The composition according to claim 133, wherein the templated molecule is non-covalently linked to the template that templated the synthesis of the templated molecule.

136. The composition according to claim 135, wherein the non-covalent linkage involves one or more bonds selected from the group consisting of hydrogen bonds, van der Waals bonds, and ionic bondings.

137. The method of any of claims 1 to 123 comprising the further step of screening a composition of bifunctional complexes each comprising a different templated molecule for templated molecules having a specific predetermined activity, said screening method comprising:

- i) obtaining a composition of different templated molecules by the method of any of claims 1 to 123,
- ii) exposing the composition of different templated molecules to conditions resulting in enrichment of templated molecules having the specific predetermined activity.

138. The method of claim 137 comprising the further step of amplifying the templated molecules of the enriched composition, thereby obtaining a second composition of templated molecules.

139. The method of claim 138, wherein the steps of exposing the composition of different templated molecules to conditions resulting in enrichment of templated molecules having the predetermined activity and amplifying the templated molecules of the enriched composition are repeated.

140. The method of claim 139, wherein said steps are repeated at least 2 times.

141. The method of claim 139, wherein said steps are repeated at least 3 times.

142. The method of claim 139, wherein said steps are repeated at least 5 times.

143. The method of any of claims 139 to 142, wherein the repetition of the method steps result in a further enriched composition of templated molecules having the specific predetermined activity.

144. The method of claim 138, further comprising the step of mutating the templated molecules, wherein said mutagenesis can take place prior to, simultaneously with, or after amplification of the templated molecules of the enriched composition.

145. The method of claim 144, wherein the mutagenesis is carried out as random or site-directed mutagenesis.

146. The method of claim 138, wherein the templated molecules of the enriched composition are amplified by a factor of from 10^1 to 10^{15} .

147. The method of claim 137 comprising the further step of identifying a templated molecule having the predetermined activity.

148. The method of claim 147, wherein the identification is conducted by analysing the template and/or the complementary template physically.

149. The method of claim 137, wherein templated molecules of the enriched fraction having the predetermined activity are obtained by binding to a binding partner immobilised on a support.

150. The method of claim 137, wherein templated molecules of the enriched fraction having the predetermined activity are obtained by electrophoretic separation, gel filtration, immunoprecipitation, isoelectric focusing, centrifugation, and immobilization.

151. The method of claim 137, wherein the predetermined activity is a catalytic activity.

Patentansprüche

1. Verfahren zur Synthese einer Zusammensetzung unterschiedlicher durch Template-bestimmter Moleküle, welche mehrere funktionelle Gruppen aufweisen, wobei das Verfahren die Schritte umfasst

- i) Bereitstellen mehrerer Templates mit unterschiedlichen codierenden Elementen und/oder einer unterschiedlichen Reihenfolge codierender Elemente, worin die Elemente mehrere Nukleotide und eine Sequenz n codierender Elemente umfassen, worin jedes codierende Element mindestens eine Erkennungsgruppe aufweist, die ein bestimmtes komplementäres Element erkennen kann, worin n eine ganze Zahl von mehr als 1 ist,
- ii) Bereitstellen mehrerer Baublöcke, wobei jeder Baublock umfasst,

- a) mindestens ein komplementäres Element, das mindestens eine Erkennungsgruppe aufweist, die ein bestimmtes codierendes Element erkennen kann,
- b) mindestens eine Funktionseinheit, die mindestens eine funktionale Gruppe und mindestens eine reaktive Gruppe umfasst, und
- c) mindestens einen Linker, der die mindestens eine Funktionseinheit von dem mindestens einen komplementären Element trennt,

iii) Inkontaktbringen eines jeden der codierenden Elemente mit einem komplementären Element, das das codierende Element erkennen kann, wobei das komplementäre Element mehrere Nukleotide enthält,

iv) Erhalten eines komplementären Templates durch enzymatisches Verknüpfen der komplementären Elemente, und

v) Erhalten einer Zusammensetzung unterschiedlicher, durch Template-bestimmter Moleküle, von denen jedes kovalent gebundene, funktionelle Gruppe umfasst, durch Verbinden einer funktionellen Gruppe mindestens einer Funktionseinheit mit einer funktionellen Gruppe einer anderen Funktionseinheit,

worin das durch Template-bestimmte Molekül mittels eines Linkers mit dem komplementären Template oder mit dem Template verbunden ist, die die Synthese des durch Template bestimmten Moleküls steuern, und
worin die Synthese des durch Template bestimmten Moleküls keine durch Ribosomen vermittelte Translation eine Nukleinsäure beinhaltet.

2. Verfahren nach Anspruch 1, wobei das durch Template-bestimmte Molekül mittels eines einzigen Linkers mit dem komplementären Template oder dem Template verbunden ist, die die Vorlage für die Synthese des durch Template bestimmten Moleküls waren.

3. Verfahren nach Anspruch 1, wobei die Schritte iii) bis v) für verschiedene Baublöcke wiederholt werden.

4. Verfahren nach Anspruch 1, wobei die n-codierenden Elemente eine lineare Sequenz bilden.

5. Verfahren nach Anspruch 1, wobei das die n codierenden Elemente umfassende Template verzweigt ist.

6. Verfahren nach Anspruch 1, wobei n einen Wert von 2 bis 200 besitzt.

7. Verfahren nach Anspruch 1, wobei n einen Wert von 2 bis 100 besitzt.

8. Verfahren nach Anspruch 1, wobei n einen Wert von 2 bis 20 besitzt.

9. Verfahren nach Anspruch 1, wobei n einen Wert von 2 bis 10 besitzt.

10. Verfahren nach Anspruch 1, wobei n einen Wert von 3 bis 100 besitzt.

11. Verfahren nach Anspruch 1, wobei n einen Wert von 3 bis 20 besitzt.

12. Verfahren nach Anspruch 1, wobei n einen Wert von 3 bis 10 besitzt.

13. Verfahren nach Anspruch 1, wobei n einen Wert von 3 bis 8 besitzt.

14. Verfahren nach Anspruch 1, wobei n einen Wert von 3 bis 6 besitzt.

15. Verfahren nach Anspruch 1, wobei n einen Wert von 4 bis 20 besitzt.

16. Verfahren nach Anspruch 1, wobei n einen Wert von 4 bis 10 besitzt.

17. Verfahren nach Anspruch 1, wobei n einen Wert von 4 bis 8 besitzt.

18. Verfahren nach Anspruch 1, wobei n einen Wert von 4 bis 6 besitzt.

19. Verfahren nach Anspruch 1, wobei n einen Wert von 5 bis 10 besitzt.

EP 1 402 024 B1

20. Verfahren nach Anspruch 1, wobei n einen Wert von 5 bis 8 besitzt.
21. Verfahren nach Anspruch 1, wobei n einen Wert von 6 bis 10 besitzt.
- 5 22. Verfahren nach Anspruch 1, wobei n einen Wert von 6 bis 8 besitzt.
23. Verfahren nach Anspruch 1, wobei das Template an einen festen Träger gebunden ist.
- 10 24. Verfahren nach Anspruch 1, wobei das Template Nukleotide umfasst oder daraus besteht, ausgewählt aus der Gruppe bestehend aus Desoxyribonukleinsäuren (DNA), Ribonukleinsäuren (RNA), Peptidnukleinsäuren (PNA), gesperrten Nukleinsäuren (LNA) und Morpholino-Sequenzen.
- 15 25. Verfahren nach Anspruch 1, wobei das Template umfasst oder im Wesentlichen besteht aus Nukleotiden, ausgewählt aus der Gruppe bestehend aus DNA, RNA, PNA, LNA und Morpholino-Sequenzen, und wobei das komplementäre Element umfasst oder im Wesentlichen besteht aus Nukleotiden, ausgewählt aus der Gruppe bestehend aus DNA, RNA, PNA, LNA und Morpholino-Sequenzen.
26. Verfahren nach Anspruch 1, wobei das Template amplifizierbar ist.
- 20 27. Verfahren nach Anspruch 2, wobei ein Einzelstrang von Template-codierenden Elementen mittels Hybridisierung an ein komplementäres Template, welches einen Einzelstrang komplementärer Elemente umfasst, eine Doppelhelix bildet.
- 25 28. Verfahren nach einem der Ansprüche 1 bis 27, wobei das Template eine Primer-Stelle beinhaltet.
29. Verfahren nach Anspruch 1, wobei die codierenden Elemente 2 bis 100 Untereinheiten umfassen oder daraus bestehen.
- 30 30. Verfahren nach Anspruch 1, wobei die codierenden Elemente 3 bis 40 Untereinheiten umfassen oder daraus bestehen.
31. Verfahren nach Anspruch 1, wobei die codierenden Elemente 3 bis 20 Untereinheiten umfassen oder daraus bestehen.
- 35 32. Verfahren nach Anspruch 1, wobei die codierenden Elemente 4 bis 40 Untereinheiten umfassen oder daraus bestehen.
33. Verfahren nach Anspruch 1, wobei die codierenden Elemente 4 bis 20 Untereinheiten umfassen oder daraus bestehen.
- 40 34. Verfahren nach Anspruch 1, wobei die codierenden Elemente 5 bis 40 Untereinheiten umfassen oder daraus bestehen.
- 45 35. Verfahren nach Anspruch 1, wobei die codierenden Elemente 5 bis 20 Untereinheiten umfassen oder daraus bestehen.
36. Verfahren nach Anspruch 1, wobei die codierenden Elemente 6 bis 40 Untereinheiten umfassen oder daraus bestehen.
- 50 37. Verfahren nach Anspruch 1, wobei die codierenden Elemente 6 bis 20 Untereinheiten umfassen oder daraus bestehen.
38. Verfahren nach Anspruch 1, wobei die codierenden Elemente 8 bis 40 Untereinheiten umfassen oder daraus bestehen.
- 55 39. Verfahren nach Anspruch 1, wobei die codierenden Elemente 8 bis 20 Untereinheiten umfassen oder daraus bestehen.

EP 1 402 024 B1

40. Verfahren nach Anspruch 1, wobei die codierenden Elemente 10 bis 40 Untereinheiten umfassen oder daraus bestehen.
- 5 41. Verfahren nach Anspruch 1, wobei die codierenden Elemente 10 bis 20 Untereinheiten umfassen oder daraus bestehen.
42. Verfahren nach Anspruch 1, wobei die codierenden Elemente 12 bis 40 Untereinheiten umfassen oder daraus bestehen.
- 10 43. Verfahren nach Anspruch 1, wobei die codierenden Elemente 12 bis 20 Untereinheiten umfassen oder daraus bestehen.
44. Verfahren nach Anspruch 1, wobei die codierenden Elemente 14 bis 40 Untereinheiten umfassen oder daraus bestehen.
- 15 45. Verfahren nach Anspruch 1, wobei die codierenden Elemente 14 bis 20 Untereinheiten umfassen oder daraus bestehen.
46. Verfahren nach Anspruch 1, wobei die codierenden Elemente 16 bis 40 Untereinheiten umfassen oder daraus bestehen.
- 20 47. Verfahren nach Anspruch 1, wobei die codierenden Elemente 18 bis 40 Untereinheiten umfassen oder daraus bestehen.
48. Verfahren nach Anspruch 1, wobei die codierenden Elemente 20 bis 40 Untereinheiten umfassen oder daraus bestehen.
- 25 49. Verfahren nach einem der Ansprüche 29 bis 48, wobei jede Untereinheit ein Nukleotid umfasst oder daraus besteht.
- 30 50. Verfahren nach Anspruch 1, wobei das komplementäre Template, das n komplementäre Elemente umfasst, eine lineare Sequenz komplementärer Elemente ist.
51. Verfahren nach Anspruch 1, wobei das komplementäre Template, das n komplementäre Elemente umfasst, verzweigt ist.
- 35 52. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 2 bis 100 aufweist.
53. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 4 bis 40 aufweist.
- 40 54. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 4 bis 20 aufweist.
55. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 8 bis 40 aufweist.
56. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 8 bis 20 aufweist.
- 45 57. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 10 bis 40 aufweist.
58. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 10 bis 20 aufweist.
- 50 59. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 12 bis 40 aufweist.
60. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 14 bis 40 aufweist.
61. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 16 bis 40 aufweist.
- 55 62. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 18 bis 40 aufweist.
63. Verfahren nach einem der Ansprüche 50 und 51, wobei n einen Wert von 20 bis 40 aufweist.

64. Verfahren nach Anspruch 1, wobei das komplementäre Template an einen festen Träger gebunden ist.
65. Verfahren nach Anspruch 1, wobei die komplementären Elemente ausgewählt sind aus der Gruppe bestehend aus Nukleotiden.
- 5 66. Verfahren nach Anspruch 1, wobei die komplementären Elemente vorzugsweise von 2 bis 100 Untereinheiten umfassen oder daraus bestehen.
- 10 67. Verfahren nach Anspruch 1, wobei die komplementären Elemente vorzugsweise von 4 bis 40 Untereinheiten umfassen oder daraus bestehen.
68. Verfahren nach Anspruch 1, wobei die komplementären Elemente vorzugsweise von 4 bis 20 Untereinheiten umfassen oder daraus bestehen.
- 15 69. Verfahren nach Anspruch 1, wobei die komplementären Elemente vorzugsweise von 6 bis 40 Untereinheiten umfassen oder daraus bestehen.
70. Verfahren nach Anspruch 1, wobei die komplementären Elemente vorzugsweise von 6 bis 20 Untereinheiten umfassen oder daraus bestehen.
- 20 71. Verfahren nach Anspruch 1, wobei die komplementären Elemente vorzugsweise von 8 bis 40 Untereinheiten umfassen oder daraus bestehen.
72. Verfahren nach Anspruch 1, wobei die komplementären Elemente vorzugsweise von 8 bis 20 Untereinheiten umfassen oder daraus bestehen.
- 25 73. Verfahren nach einem der Ansprüche 66 bis 72, wobei jede Untereinheit ein Nukleotid umfasst oder daraus besteht.
74. Verfahren nach Anspruch 1, wobei die komplementären Elemente ausgewählt sind unter Oligonukleotiden und wobei die komplementären Elemente unter Verwendung einer Ligase enzymatisch verknüpft sind.
- 30 75. Verfahren nach Anspruch 74, wobei die komplementären Element-Oligonukleotide jeweils drei oder mehr Nukleotide umfassen.
- 35 76. Verfahren nach Anspruch 75, wobei die komplementären Element-Oligonukleotide jeweils von 4 bis 100 Nukleotide umfassen.
77. Verfahren nach Anspruch 1, wobei zwei Linker unterschiedlicher Baublöcke jeweils eine Nukleotidsequenz umfassen, die durch eine reversible Wechselwirkung der Nukleotidsequenzen eine Dimerisierungsdomäne bilden können.
- 40 78. Verfahren nach einem der Ansprüche 1 bis 77, wobei das durch Template-bestimmte Molekül eine lineare Sequenz funktioneller Gruppen ist.
79. Verfahren nach einem der Ansprüche 1 bis 77, wobei das durch Template-bestimmte Molekül eine verzweigte Sequenz funktioneller Gruppen ist.
- 45 80. Verfahren nach einem der Ansprüche 1 bis 77, wobei das durch Template-bestimmte Molekül eine zyklische Sequenz funktioneller Gruppen ist.
- 50 81. Verfahren nach Anspruch 1, wobei das durch Template-bestimmte Molekül umfasst oder besteht aus, Moleküleinheiten ausgewählt aus der Gruppe von α -Peptiden, β -Peptiden, γ -Peptiden, ω -Peptiden, mono-, di- und tri-substituieren α -Peptiden, β -Peptiden, γ -Peptiden, ω -Peptiden, Peptiden, bei denen die Aminosäurereste in der L-Form oder in der D-Form vorliegen, vinyloge Peptide, Glycopoly-Peptide, Polyamide, vinyloge Sulphonamid-Peptide, Polysulphonamid, konjugierte Peptide, umfassend beispielsweise prosthetische Gruppen, Polyester, Polysaccharide, Polycarbamate, Polycarbonate, Polyharnstoffe, Polypeptidylphosphonate, Polyurethane, Azatide, N-substituierte Oligoglycine, Polyether, Ethoxyformacetaloligomere, Polthioether, Polyethylenglycole (PEG), Polyethylene, Polydisulphide, Polyarylsulphide, Polynukleotide, PNA's, LNA's Morpholinos, Oligopyrrolinon, Polyoxime, Polyimine, Polyethylenimine, Polyimide, Polyacetale, Polyacetate, Polystyrole, Polyvinyl, Lipide, Phospholipide, Glyco-
- 55

lipide, polyzyklische Verbindungen, umfassend beispielsweise aliphatische oder aromatische Ringe, einschließlich polyheterozyklische Verbindungen, Proteoglycane, und Polysiloxane.

5 82. Verfahren nach Anspruch 1, wobei die benachbarten Reste des durch Template-bestimmten Moleküls mittels einer chemischen Bindung verknüpft ist, ausgewählt aus der Gruppe von chemischen Bindungen bestehend aus Pep-
tidbindungen, Sulfonamidbindungen, Esterbindungen, Saccharidbindungen, Carbamatbindungen, Carbonatbin-
dungen, Harnstoff bindungen, Phosphonatbindungen, Urethanbindungen, Azatidbindungen, peptoid Bindungen,
10 Etherbindungen, Ethoxybindungen, Thioetherbindungen, Kohlenstoff-Einzelbindungen, Kohlenstoff-Doppelbindun-
gen, Kohlenstoff-Dreifachbindungen, Disulfidbindungen, Sulfidbindungen, Phosphodiesterbindungen, Oximbindun-
gen, Iminbindungen, Imidbindungen.

83. Verfahren nach Anspruch 82, wobei die chemische Bindung, über die Funktionseinheiten von zwei oder mehreren
Baublöcken verbunden sind, durch eine Reaktion einer nukleophilen Gruppe einer ersten Funktionseinheit mit einem
15 Ester oder Thioester oder einer andere Funktionseinheit gebildet wird.

84. Verfahren nach Anspruch 82, wobei der Linker des Baublocks, der die Thioestergruppe trägt, gleichzeitig mit der
Bildung der Bindung, die zu einem Transfer der funktionellen Gruppe zu dem nukleophilen Baublock führt, gespalten
wird.

20 85. Verfahren nach einem der Ansprüche 83 und 84, wobei die nukleophile Gruppe ausgewählt ist unter $-NH_2$, H_2NHN- ,
 $HOHN-$, $H_2N-C(O)-NH-$.

86. Verfahren nach Anspruch 1, wobei die Rückgrat-Struktur des durch Template-bestimmten Moleküls umfasst oder
im Wesentlichen besteht aus einer molekularen Gruppe, ausgewählt unter $NHN(R)CO-$; $-NHB(R)CO-$; $-NHC(RR')$
25 $CO-$; $-NHC(=CHR)CO-$; $-NHC_6H_4CO-$; $-NHCH_2CHRCO-$; $-NHCHRCH_2CO-$; $-COCH_2-$; $-COS-$; $-CONR-$; $-COO-$;
 $-CSNH-$; $-CH_2NH-$; $-CH_2CH_2-$; $-CH_2S-$; $-CH_2SO-$; $-CH_2SO_2-$; $-CH(CH_3)S-$; $-CH=CH-$; $-NHCO-$; $-NHCONH-$;
 $-CONHO-$; $-C(=CH_2)CH_2-$; $-PO_2-NH-$; $-PO_2-CH_2-$; $-PO_2-CH_2N^+-$; $-SO_2NH-$ und Lactamen.

30 87. Verfahren nach Anspruch 1, wobei eine funktionelle Gruppe mindestens einer Funktionseinheit mit einer anderen
Funktionseinheit mittels eines Brückenmoleküls verknüpft ist.

88. Verfahren nach Anspruch 1, wobei das durch Template-bestimmte Molekül umfasst oder im Wesentlichen besteht
aus mindestens 2 unterschiedlichen funktionellen Gruppen.

35 89. Verfahren nach Anspruch 1, wobei das durch Template-bestimmte Molekül umfasst oder im Wesentlichen besteht
aus mindestens 3 unterschiedlichen funktionellen Gruppen.

90. Verfahren nach Anspruch 1, wobei das durch Template-bestimmte Molekül umfasst oder im Wesentlichen besteht
aus mindestens 4 unterschiedlichen funktionellen Gruppen.

40 91. Verfahren nach Anspruch 1, wobei das durch Template-bestimmte Molekül umfasst oder im Wesentlichen besteht
aus mindestens 5 unterschiedlichen funktionellen Gruppen.

45 92. Verfahren nach Anspruch 1, wobei die Funktionseinheit komplementäre Element eines jeden Baublocks mindestens
eine reaktive Gruppe vom Typ I umfasst.

93. Verfahren nach Anspruch 1, wobei die Funktionseinheit eines jeden Baublocks mindestens eine reaktive Gruppe
vom Typ II umfasst.

50 94. Verfahren nach Anspruch 1, wobei das komplementäre Element eines jeden Baublocks mindestens zwei reaktive
Gruppen vom Typ I umfasst.

95. Verfahren nach Anspruch 1, wobei die Funktionseinheit eines jeden Baublocks mindestens zwei reaktive Gruppen
vom Typ II umfasst.

55 96. Verfahren nach Anspruch 1, wobei die Funktionseinheit eines jeden Baublocks mindestens drei oder vier reaktive
Gruppen vom Typ II umfasst.

97. Verfahren nach einem der Ansprüche 95 und 96, wobei die zwei reaktive Gruppen vom Typ II Reaktionspartner sind.

98. Verfahren nach Anspruch 97, wobei die reaktiven Gruppen vom Typ II eine Bindung zwischen den funktionellen Gruppen durch ein Brückenmolekül bilden können.

99. Verfahren nach Anspruch 98, wobei das Brückenmolekül eine bifunktionelle Verbindung ist, die reaktive Gruppen aufweist, die für die reaktive Gruppen vom Typ II der Funktionseinheiten Reaktionspartner sind.

100. Verfahren nach Anspruch 95, wobei die reaktiven Gruppen vom Typ II unterschiedliche Reaktionspartner sind.

101. Verfahren nach Anspruch 100, wobei die unterschiedlichen reaktiven Gruppen vom Typ II zwischen den funktionellen Gruppen eine Verbindung über ein Brückenmolekül bilden können.

102. Verfahren nach Anspruch 101, wobei das Brückenmolekül eine bifunktionelle Verbindung ist, mit reaktiven Gruppen, die für die reaktiven Gruppen vom Typ II der Funktionseinheiten Reaktionspartner sind.

103. Verfahren nach einem der Ansprüche 95 bis 102, wobei die mindestens eine reaktive Gruppe vom Typ II der Funktionseinheit ausgewählt ist aus der Gruppe bestehend aus N-Carboxyanhydrid (NCA), N-Thiocarboxyanhydride (NTA), Coumarin, Amin, Carbonsäure, Keton, Aldehyd, Hydroxy, Thiol, Ester, Thioester, Alkenyl, jedes konjugierte System von Doppelbindungen, Hydrazin, N-Hydroxysuccinimidester, und Epoxid.

104. Verfahren nach einem der Ansprüche 95 bis 102, wobei die reaktive Gruppe vom Typ II ein Elektrophil ist.

105. Verfahren nach Anspruch 104, wobei die reaktive Gruppe vom Typ II ein Elektrophil ist ausgewählt aus der Gruppe bestehend aus $-X-C(O)-R$, $-X-C(O)CHR-C(O)-R$, $-X-C(O)-CR=CH-R$, und $-X-C(O)-CHR-NHR$, worin X S oder O ist, und R unabhängig eine funktionelle Gruppe ist.

106. Verfahren nach einem der Ansprüche 95 bis 102, wobei die reaktive Gruppe vom Typ II ein Nukleophil ist.

107. Verfahren nach Anspruch 106, wobei die reaktive Gruppe vom Typ II ein Nukleophil ist, ausgewählt aus der Gruppe bestehend aus $-NH_2$, H_2NHN- , $HOHN-$ und $H_2N-C(O,S)-NH-$.

108. Verfahren nach einem der Ansprüche 95 bis 102, wobei die reaktive Gruppe vom Typ II ein Radikal ist.

109. Verfahren nach einem der vorstehenden Ansprüche, wobei eine Funktionseinheit hinsichtlich der Rotation beschränkt ist, um während der Bildung von Bindungen mit anderen Funktionseinheiten eine bevorzugte Orientierung zu erhalten.

110. Verfahren nach einem der vorstehenden Ansprüche, wobei die Bildung des durch Template-bestimmten Moleküls reaktive Gruppen vom Typ II beinhaltet, die über anionische, kationische oder Radikal-Polymerisation ein Polymer bilden können.

111. Verfahren nach einem der vorstehenden Ansprüche, welches eine Gerüst-Funktionseinheit umfasst, die ein oder mehrere reaktive Gruppen vom Typ II umfasst, wobei die Gerüst-Funktionseinheit die chemische Basisstruktur zur Bildung eines durch Template-bestimmten Moleküls durch Zusatz funktioneller Gruppen, die von den mehreren Baublocken entstammen, darstellt.

112. Verfahren nach Anspruch 111, wobei die Gerüst-Funktionseinheit zwei oder mehrere reaktive Gruppen vom Typ II umfasst.

113. Verfahren nach einem der Ansprüche 111 und 112, wobei die Gerüst-Funktionseinheit mit dem Template funktionell verknüpft ist.

114. Verfahren nach einem der Ansprüche 111 und 112, wobei die Gerüst-Funktionseinheit mit einem komplementären Element verknüpft ist, das ein codierendes Element des Templates erkennen kann.

115. Verfahren nach einem der Ansprüche 111 bis 114, wobei eine Verschlüsselung der Bindung funktioneller Gruppen an die Gerüst-Funktionseinheit erhalten wird, indem eine unterschiedliche Anzahl reaktiver Gruppen vom Typ II an

der Gerüst-Funktionseinheit vorgesehen ist im Vergleich zu der Anzahl reaktiver Gruppen vom Typ II an den Funktionseinheiten der mehreren Baublöcke.

5 **116.**Verfahren nach einem der Ansprüche 111 bis 115, wobei die Reaktion der reaktiven Gruppen vom Typ II am Gerüst und die entsprechenden reaktiven Gruppen vom Typ II an den Baublöcken zu einer Verknüpfung der funktionellen Gruppen mit der Gerüst-Funktionseinheit und gleichzeitigen Abspaltung des Linkers, der die Funktionseinheit mit dem komplementären Element verbindet, führt.

10 **117.**Verfahren nach Anspruch 1, wobei vier oder mehrere unterschiedliche Templates verwendet werden.

118.Verfahren nach Anspruch 1, wobei 10^3 unterschiedliche Templates verwendet werden.

119.Verfahren nach Anspruch 1, wobei 10^5 unterschiedliche Templates verwendet werden.

15 **120.**Verfahren nach Anspruch 1, wobei 10^7 unterschiedliche Templates verwendet werden.

121.Verfahren nach Anspruch 1, wobei die mehreren unterschiedlichen Templates zur Bildung einer Bank unterschiedlicher, durch Template-bestimmter Molekül führen, wobei jedes der durch Template-bestimmten Moleküle mit dem spezifischen Template verbunden ist, das die Vorlage für die Synthese des Moleküls war.

20 **122.**Verfahren nach Anspruch 1, wobei die mehreren unterschiedlichen Templates zur Bildung einer Bank unterschiedlicher, durch Template-bestimmter Moleküle führen, wobei jedes der durch Template-bestimmten Moleküle mit dem spezifischen komplementären Template verbunden ist, das die Vorlage für die Synthese des Moleküls war.

25 **123.**Verfahren nach einem der vorstehenden Ansprüche, welches weiter den Schritt umfasst, Freisetzen des Templates oder komplementären Templates von dem durch Template-bestimmten Molekül, und Erhalten eines durch Template-bestimmten Moleküls, das nicht mit dem komplementären Template oder dem Template, die die Vorlage für die Synthese des durch Template bestimmten Moleküls waren, verbunden ist.

30 **124.**Zusammensetzung unterschiedlicher, durch Template-bestimmter Moleküle, worin jedes der durch Template-bestimmten Moleküle mit dem spezifischen komplementären Template verbunden ist, das die Vorlage für die Synthese des durch Template-bestimmten Moleküls war, worin die durch Template-bestimmten Moleküle keine α -Peptide sind, und worin die Zusammensetzung durch das Verfahren nach Anspruch 122 erhalten wird.

35 **125.**Zusammensetzung nach Anspruch 124, worin die Zusammensetzung eine Vielzahl von etwa 10^3 unterschiedlichen, durch Template-bestimmten Moleküle umfasst.

126.Zusammensetzung nach Anspruch 124, worin die Zusammensetzung eine Vielzahl von etwa 10^4 unterschiedlichen, durch Template-bestimmten Moleküle umfasst.

40 **127.**Zusammensetzung nach Anspruch 124, worin die Zusammensetzung eine Vielzahl von etwa 10^5 unterschiedlichen, durch Template-bestimmten Moleküle umfasst.

45 **128.**Zusammensetzung nach Anspruch 124, worin die Zusammensetzung eine Vielzahl von etwa 10^6 unterschiedlichen, durch Template-bestimmten Moleküle umfasst.

129.Zusammensetzung nach Anspruch 124, worin die Zusammensetzung eine Vielzahl von etwa 10^7 unterschiedlichen, durch Template-bestimmten Moleküle umfasst.

50 **130.**Zusammensetzung nach Anspruch 124, worin die Zusammensetzung eine Vielzahl von etwa 10^8 unterschiedliche, durch Template-bestimmte Moleküle umfasst.

131.Zusammensetzung nach Anspruch 124, worin die Zusammensetzung eine Vielzahl von etwa 10^9 unterschiedlichen, durch Template-bestimmten Moleküle umfasst.

55 **132.**Zusammensetzung nach Anspruch 124, worin die Zusammensetzung eine Vielzahl von etwa 10^{10} unterschiedlichen, durch Template-bestimmten Moleküle umfasst.

133. Zusammensetzung nach einem der Ansprüche 124 bis 132, weiter umfassend die Templates, die die Vorlage für die Synthese der unterschiedlichen, durch Template- bestimmten Moleküle waren, oder eine Untergruppe davon.

134. Zusammensetzung nach Anspruch 133, worin das durch Template-bestimmte Molekül mit dem Template kovalent verknüpft ist, das die Vorlage für die Synthese des durch Template-bestimmten Moleküls war.

135. Zusammensetzung nach Anspruch 133, worin das durch Template-bestimmte Molekül mit dem Template kovalent verknüpft ist, das die Vorlage für die Synthese des durch Template-bestimmten Moleküls war.

136. Zusammensetzung nach Anspruch 135, worin die nicht-kovalente Verknüpfung ein oder mehrere Bindungen beinhaltet, ausgewählt aus der Gruppe bestehend aus Wasserstoffbrückenbindungen, van der Waals Bindungen und ionischen Bindungen.

137. Verfahren nach einem der Ansprüche 1 bis 123, weiter den Schritt umfassend, Durchmustern einer Zusammensetzung bifunktioneller Komplexe, von denen jeder ein unterschiedliches, durch Template-bestimmtes Molekül für durch Template-bestimmte Moleküle mit einer spezifischen bestimmten Aktivität umfasst, wobei das Durchmusterverfahren umfasst:

i) Erhalten einer Zusammensetzung unterschiedlicher, durch Template-bestimmter Moleküle durch das Verfahren nach einem der Ansprüche 1 bis 123,

ii) Aussetzen der Zusammensetzung unterschiedlicher, durch Template-bestimmter Moleküle an Bedingungen, die zu einer Anreicherung der durch Template-bestimmten Moleküle mit der spezifischen bestimmten Aktivität führen.

138. Verfahren nach Anspruch 137, welches weiter den Schritt umfasst, Amplifizieren des durch Template bestimmten Moleküls der angereicherten Zusammensetzung, wodurch eine zweite Zusammensetzung der durch Template-bestimmten Moleküle erhalten wird.

139. Verfahren nach Anspruch 138, wobei die Schritte des Aussetzens der Zusammensetzung unterschiedlicher, durch Template-bestimmter Moleküle an Bedingungen, die zu einer Anreicherung der durch Template-bestimmten Moleküle mit der bestimmten Aktivität führen, und des Amplifizierens der durch Template-bestimmten Moleküle, wiederholt werden.

140. Verfahren nach Anspruch 139, wobei die Schritte mindestens zweimal wiederholt werden.

141. Verfahren nach Anspruch 139, wobei die Schritte mindestens dreimal wiederholt werden.

142. Verfahren nach Anspruch 139, wobei die Schritte mindestens fünfmal wiederholt werden.

143. Verfahren nach einem der Ansprüche 139 bis 142, wobei die Wiederholung der Verfahrensschritte zu einer weiteren angereicherten Zusammensetzung der durch Template-bestimmten Moleküle mit der spezifischen bestimmten Aktivität führen.

144. Verfahren nach Anspruch 138, weiter den Schritt umfassend, Mutieren der durch Template-bestimmten Moleküle, wobei die Mutagenese vor, gleichzeitig mit oder nach Amplifizieren der durch Template-bestimmten Moleküle der angereicherten Zusammensetzung stattfinden kann.

145. Verfahren nach Anspruch 144, wobei die Mutagenese als zufällige oder Stellengerichtete Mutagenese ausgeführt wird.

146. Verfahren nach Anspruch 138, wobei die durch Template-bestimmten Moleküle der angereicherten Zusammensetzung um einen Faktor von 10^1 bis 10^{15} amplifiziert werden.

147. Verfahren nach Anspruch 137, weiter den Schritt umfassend, Identifizieren eines durch Template-bestimmten Moleküls mit einer bestimmten Aktivität.

148. Verfahren nach Anspruch 147, wobei die Identifizierung durch Analyse des Templates und/oder des komplementären Templates körperlich durchgeführt wird.

149. Verfahren nach Anspruch 137, wobei die durch Template-bestimmten Moleküle der angereicherten Fraktion mit der bestimmten Aktivität durch Binden an einen Bindungspartner erhalten werden, der an einem Träger immobilisiert ist,.

150. Verfahren nach Anspruch 137, wobei die durch Template-bestimmten Moleküle durch elektrophoretische Trennung, Gelfiltration, Immunpräzipitierung, isoelektrisches Fokussieren, Zentrifugieren und Immobilisieren erhalten werden.

151. Verfahren nach Anspruch 137, wobei die bestimmte Aktivität eine katalytische Aktivität ist.

Revendications

1. Procédé pour la synthèse d'une composition de différentes molécules matricées comprenant une pluralité de groupes fonctionnels, ledit procédé comprenant les étapes consistant à

i) fournir une pluralité de matrices ayant des éléments codants différents et/ou un ordre différent d'éléments codants, lesdites matrices comprenant une pluralité de nucléotides et une séquence de n éléments codants, dans laquelle chaque élément codant comprend au moins un groupe de reconnaissance capable de reconnaître un élément complémentaire prédéterminé, et

dans laquelle n est un nombre entier supérieur à 1,

ii) fournir une pluralité de synthons, dans laquelle chaque synthon comprend

a) au moins un élément complémentaire comprenant au moins un groupe de reconnaissance capable de reconnaître un élément codant prédéterminé,

b) au moins une entité fonctionnelle comprenant au moins un groupe fonctionnel et au moins un groupe réactif, et

c) au moins un lieu séparant ledit au moins groupe fonctionnel dudit au moins élément complémentaire,

iii) mettre en contact chacun desdits éléments codants avec un élément complémentaire capable de reconnaître ledit élément codant, ledit élément complémentaire comprenant une pluralité de nucléotides,

iv) obtenir une matrice complémentaire en liant de manière enzymatique les éléments complémentaires, et

v) obtenir une composition de différentes molécules matricées chacune comprenant des groupes fonctionnels liés de manière covalente en liant un groupe fonctionnel d'au moins une entité fonctionnelle à un groupe fonctionnel d'une autre entité fonctionnelle,

dans laquelle la molécule matricée est liée au moyen d'un lieu à la matrice complémentaire ou à la matrice qui a servi de matrice pour la synthèse de la molécule à matrice, et

dans laquelle la synthèse des molécules matricées n'implique pas de traduction médiée par ribosome d'un acide nucléique.

2. Procédé selon la revendication 1, dans lequel la molécule matricée est liée au moyen d'un lieu simple à la matrice complémentaire ou à la matrice qui a servi de matrice pour la synthèse de la molécule matricée.

3. Procédé selon la revendication 1, dans lequel les étapes iii) à v) sont répétées pour différents synthons.

4. Procédé selon la revendication 1, dans lequel les n éléments codants forment une séquence linéaire.

5. Procédé selon la revendication 1, dans lequel la matrice comprenant n éléments codants est ramifiée.

6. Procédé selon la revendication 1, dans lequel n a une valeur allant de 2 à 200.

7. Procédé selon la revendication 1, dans lequel n a une valeur allant de 2 à 100.

8. Procédé selon la revendication 1, dans lequel n a une valeur allant de 2 à 20.

9. Procédé selon la revendication 1, dans lequel n a une valeur allant de 2 à 10.

10. Procédé selon la revendication 1, dans lequel n a une valeur allant de 3 à 100

EP 1 402 024 B1

11. Procédé selon la revendication 1, dans lequel n a une valeur allant de 3 à 20.
12. Procédé selon la revendication 1, dans lequel n a une valeur allant de 3 à 10.
- 5 13. Procédé selon la revendication 1, dans lequel n a une valeur allant de 3 à 8.
14. Procédé selon la revendication 1, dans lequel n a une valeur allant de 3 à 6.
15. Procédé selon la revendication 1, dans lequel n a une valeur allant de 4 à 20.
- 10 16. Procédé selon la revendication 1, dans lequel n a une valeur allant de 4 à 10.
17. Procédé selon la revendication 1, dans lequel n a une valeur allant de 4 à 8.
- 15 18. Procédé selon la revendication 1, dans lequel n a une valeur allant de 4 à 6.
19. Procédé selon la revendication 1, dans lequel n a une valeur allant de 5 à 10.
20. Procédé selon la revendication 1, dans lequel n a une valeur allant de 5 à 8.
- 20 21. Procédé selon la revendication 1, dans lequel n a une valeur allant de 6 à 10.
22. Procédé selon la revendication 1, dans lequel n a une valeur allant de 6 à 8.
- 25 23. Procédé selon la revendication 1, dans lequel la matrice est attachée à un support solide.
24. Procédé selon la revendication 1, dans lequel la matrice comprend ou est constituée de nucléotides sélectionnés parmi le groupe constitué des acides désoxyribonucléiques (ADN), des acides ribonucléiques (ARN), des acides nucléiques peptidiques (APN), des acides nucléiques verrouillés (LNA), et des séquences morpholino.
- 30 25. Procédé selon la revendication 1, dans lequel la matrice comprend ou est essentiellement constituée de nucléotides sélectionnés parmi le groupe constitué d'ADN, d'ARN, d'APN, de LNA et de séquence morpholinos, et dans lequel l'élément complémentaire comprend ou est essentiellement constitué de nucléotides sélectionnés parmi le groupe constitué d'ADN, d'ARN, d'APN, de LNA et de séquences morpholino.
- 35 26. Procédé selon la revendication 1, dans lequel la matrice est amplifiable.
27. Procédé selon la revendication 26, dans lequel un brin simple des éléments codants de la matrice forme une double hélice par hybridation à une matrice complémentaire comprenant un brin simple des éléments complémentaires.
- 40 28. Procédé selon l'une quelconque des revendications 1 à 27, dans lequel la matrice comprend un site d'amorçage.
29. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 2 à 100 sous-unités.
- 45 30. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 3 à 40 sous-unités.
31. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 3 à 20 sous-unités.
- 50 32. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 4 à 40 sous-unités.
- 55 33. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 4 à 20 sous-unités.
34. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 5 à 40

sous-unités.

- 5 35. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 5 à 20 sous-unités.
36. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 6 à 40 sous-unités.
- 10 37. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 6 à 20 sous-unités.
38. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 8 à 40 sous-unités.
- 15 39. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 8 à 20 sous-unités.
40. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 10 à 40 sous-unités.
- 20 41. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 10 à 20 sous-unités.
- 25 42. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 12 à 40 sous-unités.
43. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 12 à 20 sous-unités.
- 30 44. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 14 à 40 sous-unités.
45. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 14 à 20 sous-unités.
- 35 46. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 16 à 40 sous-unités.
- 40 47. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 18 à 40 sous-unités.
48. Procédé selon la revendication 1, dans lequel les éléments codants comprennent ou sont constitués de 20 à 40 sous-unités.
- 45 49. Procédé selon l'une quelconque des revendications 29 à 48, dans lequel chaque sous-unité comprend ou est constituée d'un nucléotide.
- 50 50. Procédé selon la revendication 1, dans lequel la matrice complémentaire comprenant n éléments complémentaires est une séquence linéaire d'éléments complémentaires.
51. Procédé selon la revendication 1, dans lequel la matrice complémentaire comprenant n éléments complémentaires est ramifiée.
- 55 52. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 2 à 100.
53. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 4 à 40.
54. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 4 à 20.

EP 1 402 024 B1

55. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 8 à 40.
56. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 8 à 20.
- 5 57. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 10 à 40.
58. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 10 à 20.
59. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 12 à 40.
- 10 60. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 14 à 40.
61. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 16 à 40.
- 15 62. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 18 à 40.
63. Procédé selon l'une quelconque des revendications 50 et 51, dans lequel n a une valeur allant de 20 à 40.
- 20 64. Procédé selon la revendication 1, dans lequel la matrice complémentaire est attachée à un support solide.
65. Procédé selon la revendication 1, dans lequel les éléments complémentaires sont sélectionnés parmi le groupe constitué des nucléotides.
- 25 66. Procédé selon la revendication 1, dans lequel les éléments complémentaires de préférence comprennent ou sont constitués de 2 à 100 sous-unités.
67. Procédé selon la revendication 1, dans lequel les éléments complémentaires de préférence comprennent ou sont constitués de 4 à 40 sous-unités.
- 30 68. Procédé selon la revendication 1, dans lequel les éléments complémentaires de préférence comprennent ou sont constitués de 4 à 20 sous-unités.
69. Procédé selon la revendication 1, dans lequel les éléments complémentaires de préférence comprennent ou sont constitués de 6 à 40 sous-unités.
- 35 70. Procédé selon la revendication 1, dans lequel les éléments complémentaires de préférence comprennent ou sont constitués de 6 à 20 sous-unités.
- 40 71. Procédé selon la revendication 1, dans lequel les éléments complémentaires de préférence comprennent ou sont constitués de 8 à 40 sous-unités.
72. Procédé selon la revendication 1, dans lequel les éléments complémentaires de préférence comprennent ou sont constitués de 8 à 20 sous-unités.
- 45 73. Procédé selon l'une quelconque des revendications 66 à 72, dans lequel chaque sous-unité comprend ou est constituée d'un nucléotide.
74. Procédé selon la revendication 1, dans lequel les éléments complémentaires sont sélectionnés parmi des oligonucléotides et les éléments complémentaires sont liés de manière enzymatique en utilisant une ligase.
- 50 75. Procédé selon la revendication 74, dans lequel les oligonucléotides des éléments complémentaires comprennent chacun trois nucléotides ou plus.
76. Procédé selon la revendication 75, dans lequel les oligonucléotides des éléments complémentaires comprennent chacun de 4 à 100 nucléotides.
- 55 77. Procédé selon la revendication 1, dans lequel deux lieurs de synthons distincts comprennent chacun une séquence nucléotidique capable de former un domaine de dimérisation par interaction réversible des séquences nucléotidi-

ques.

78. Procédé selon l'une quelconque des revendications 1 à 77, dans lequel la molécule matricée est une séquence linéaire de groupes fonctionnels.

79. Procédé selon l'une quelconque des revendications 1 à 77, dans lequel la molécule matricée est une séquence ramifiée des groupes fonctionnels.

80. Procédé selon l'une quelconque des revendications 1 à 77, dans lequel la molécule matricée est une séquence cyclique de groupes fonctionnels.

81. Procédé selon la revendication 1, dans lequel la molécule matricée comprend ou est constituée d'entités moléculaires sélectionnées parmi le groupe des α -peptides, des β -peptides, des γ -peptides, des ω -peptides, des α -peptides, β -peptides, γ -peptides, ω -peptides mono-, di- et tri-substitués, des peptides dans lesquels les résidus d'acides aminés sont sous forme de L ou sous forme de D, des polypeptides vinylogues, des glycopoly-peptides, des polyamides, un peptide sulfonamide vinylogue, un polysulfonamide, des peptides conjugués comprenant par exemple des groupes prosthétiques, des polyesters, des polysaccharides, des polycarbamates, des polycarbonates, des polyurées, des polypeptidylphosphonates, des polyuréthanes, des azatides, des oligomères glycines N-substituées, des polyéthers, des oligomères éthoxyformacétal, des polythioéthers, des polyéthylèneglycols (PEG), des polyéthylènes, des polydisulfures, des sulfures polyaryliènes, des polynucléotides, des APN, des LNA, des morpholinos, des oligo pyrrolinonc, des polyoximes, des polyimines, des polyéthylèneimines, des polyimides, des polyacétals, des polyacétates, des polystyrènes, du polyvinyle, des lipides, des phospholipides, des glycolipides, des composés polycycliques comprenant par exemple des cycles aliphatiques ou aromatiques, y compris des composés polyhétérocycliques, des protéoglycanes, et des polysiloxanes.

82. Procédé selon la revendication 1, dans lequel les résidus voisins de la molécule matricée sont liés par une liaison chimique sélectionnée parmi le groupe des liaisons chimiques constitué des liaisons peptidiques, des liaisons sulfonamides, des liaisons esters, des liaisons saccharides, des liaisons carbamates, des liaisons carbonates, des liaisons urées, des liaisons phosphonate, des liaisons uréthane, des liaisons azatides, des liaisons peptoides, des liaisons éther, des liaisons éthoxy, des liaisons thioéther, des liaisons carbone simples, des liaisons carbone doubles, des liaisons carbone triples, des liaisons disulfures, des liaisons sulfures, des liaisons phosphodiester, des liaisons oxime, des liaisons imines, des liaisons imides.

83. Procédé selon la revendication 82, dans lequel la liaison chimique liant les entités fonctionnelles de deux synthons ou plus est formée par une réaction d'un groupe nucléophile d'une première entité fonctionnelle avec un ester ou un thioester d'une autre entité fonctionnelle.

84. Procédé selon la revendication 82, dans lequel le lieu du synthon portant le groupe thioester est clivé simultanément avec la formation de la liaison ayant pour résultat un transfert de groupe fonctionnel au synthon nucléophile.

85. Procédé selon l'une quelconque des revendications 83 et 84, dans lequel le groupe nucléophile est sélectionné parmi -NH_2 , $\text{H}_2\text{NHN-}$, HOHN- , $\text{H}_2\text{N-C(O)-NH-}$.

86. Procédé selon la revendication 1, dans lequel la structure du squelette desdites molécules matricées comprend ou est constituée d'un groupe moléculaire sélectionné parmi -NHN(R)CO- ; -NHB(R)CO- ; -NHC(RR')CO- ; -NHC(=CHR)CO- ; $\text{-NHC}_6\text{H}_4\text{CO-}$; $\text{-NHCH}_2\text{CHRCO-}$; $\text{-NHCHRCH}_2\text{CO-}$; $\text{-COCH}_2\text{-}$; -COS- ; -CONR- ; -COO- ; -CSNH- ; $\text{-CH}_2\text{NH-}$; $\text{-CH}_2\text{CH}_2\text{-}$; $\text{-CH}_2\text{S-}$; $\text{-CH}_2\text{SO-}$; $\text{-CH}_2\text{SO}_2\text{-}$; $\text{-CH(CH}_3\text{)S-}$; -CH=CH- ; -NHCO- ; -NHCONH- ; -CONHO- ; $\text{-C(=CH}_2\text{)CH}_2\text{-}$; $\text{-PO}_2\text{-NH-}$; $\text{-PO}_2\text{-CH}_2\text{-}$; $\text{-PO}_2\text{-CH}_2\text{N}^+\text{-}$; $\text{-SO}_2\text{NH-}$; et les lactames.

87. Procédé selon la revendication 1, dans lequel un groupe fonctionnel d'au moins une entité fonctionnelle est lié à une autre entité fonctionnelle au moyen d'une molécule de pontage.

88. Procédé selon la revendication 1, dans lequel les molécules matricées comprennent ou sont constituées d'au moins 2 groupes fonctionnels différents.

89. Procédé selon la revendication 1, dans lequel les molécules matricées comprennent ou sont constituées d'au moins 3 groupes fonctionnels différents.

90. Procédé selon la revendication 1, dans lequel les molécules matricées comprennent ou sont constituées d'au moins 4 groupes fonctionnels différents,
- 5 91. Procédé selon la revendication 1, dans lequel les molécules matricées comprennent ou sont constituées d'au moins 5 groupes fonctionnels différents.
92. Procédé selon la revendication 1, dans lequel l'élément complémentaire de chaque synthon comprend au moins un groupe réactif de type I.
- 10 93. Procédé selon la revendication 1, dans lequel l'entité fonctionnelle de chaque synthon comprend au moins un groupe réactif de type 11.
94. Procédé selon la revendication 92, dans lequel l'élément complémentaire de chaque synthon comprend deux groupes réactifs de type I.
- 15 95. Procédé selon la revendication 93, dans lequel l'entité fonctionnelle de chaque synthon comprend deux groupes réactifs de type II.
96. Procédé selon la revendication 93, dans lequel l'entité fonctionnelle d'au moins un synthon comprend trois ou quatre groupes réactifs de type II.
- 20 97. Procédé selon l'une quelconque des revendications 95 et 96, dans lequel les groupes réactifs de type II sont des partenaires réactionnels.
- 25 98. Procédé selon la revendication 97, dans lequel les groupes réactifs de type II sont capables de former une liaison entre les groupes fonctionnels par une molécule de pontage.
99. Procédé selon la revendication 98, dans lequel la molécule de pontage est un composé difonctionnel avec des groupes réactifs qui sont des partenaires réactionnels des groupes réactifs de type II des entités fonctionnelles.
- 30 100. Procédé selon la revendication 95, dans lequel les groupes réactifs de type II sont des partenaires réactionnels différents.
101. Procédé selon la revendication 100, dans lequel les différents groupes réactifs de type II sont capables de former une liaison entre les groupes fonctionnels par une molécule de pontage.
- 35 102. Procédé selon la revendication 101, dans lequel la molécule de pontage est un composé di-fonctionnel avec des groupes réactifs qui sont des partenaires réactionnels des groupes réactifs de type II des entités fonctionnelles.
- 40 103. Procédé selon l'une quelconque des revendications 95 à 102, dans lequel au moins un groupe réactif de type II de l'entité fonctionnelle est sélectionné parmi le groupe constitué du N-carboxyanhydride (NCA), du N-thiocarboxyanhydride (NTA), de la coumarine, de l'amine, de l'acide carboxylique, de la cétone, de l'aldéhyde, de l'hydroxyle, du thiol, de l'ester, du thioester, de l'alkenyl, de tout système conjugué de liaisons doubles, de l'hydrazine, du N-hydroxysuccinimide ester, et de l'époxyde.
- 45 104. Procédé selon l'une quelconque des revendications 95 à 102, dans lequel le groupe réactif de type 11 est un électrophile.
105. Procédé selon la revendication 104, dans lequel le groupe réactif de type II est un électrophile sélectionné parmi le groupe constitué de -X-C(O)-R, -X-C(O)-CHRC(O)-R, -X-C(O)-CR=CH-R, et -X-C(O)-CHR-NHR, dans lequel X est S ou O, et R indépendamment est un groupe fonctionnel.
- 50 106. Procédé selon l'une quelconque des revendications 95 à 102, dans lequel le groupe réactif de type II est un nucléophile.
- 55 107. Procédé selon la revendication 106, dans lequel le groupe réactif de type II est un nucléophile sélectionné parmi le groupe constitué de -NH₂, H₂NHN-, HOHN-, et H₂N-C(O,S)-NH-.

108. Procédé selon les revendications 95 à 102, dans lequel le groupe réactif de type II est un radical.

109. Procédé selon l'une quelconque des revendications précédentes, dans lequel une entité fonctionnelle est restreinte à la rotation afin d'obtenir une orientation préférée au cours de la formation des liaisons à d'autres entités fonctionnelles.

110. Procédé selon l'une quelconque de revendications précédentes, dans lequel la formation de la molécule matricée implique des groupes réactifs de type II capables de former un polymère par polymérisation anionique, cationique, ou radicalaire.

111. Procédé selon l'une quelconque de revendications précédentes, comprenant une entité fonctionnelle de scaffold comprenant un de plusieurs groupes réactifs de type II, ladite entité fonctionnelle de scaffold étant la structure chimique basique pour la formation d'une molécule matricée par addition de groupes fonctionnels émanant de la pluralité de synthons.

112. Procédé selon la revendication 111, dans lequel l'entité fonctionnelle de scaffold comprend deux groupes réactifs de type II ou plus.

113. Procédé selon l'une quelconque des revendications 111 et 112, dans lequel l'entité fonctionnelle de scaffold est liée de manière covalente à la matrice.

114. Procédé selon l'une quelconque des revendications 111 et 112, dans lequel l'entité fonctionnelle de scaffold est liée à un élément complémentaire capable de reconnaître un élément codant de la matrice.

115. Procédé selon l'une quelconque des revendications 111 à 114, dans lequel un embrouillage de la liaison des groupes fonctionnels à l'entité fonctionnelle de scaffold est obtenu en ayant un nombre différent de groupes réactifs de type II sur l'entité fonctionnelle de scaffold comparé au nombre de groupes réactifs de type II sur les entités fonctionnelles de la pluralité de synthons.

116. Procédé selon l'une quelconque des revendications III à 115, dans lequel la réaction des groupes réactifs de type II sur le scaffold et des groupes réactifs de type II correspondants sur les synthons a pour résultat une liaison simultanée des groupes fonctionnels à l'entité fonctionnelle de scaffold et le clivage du lieu connectant l'entité fonctionnelle avec l'élément complémentaire.

117. Procédé selon la revendication 1, dans lequel quatre matrices différentes ou plus sont utilisées.

118. Procédé selon la revendication 1, dans lequel plus de 10^3 matrices différentes sont utilisées.

119. Procédé selon la revendication 1, dans lequel plus de 10^5 matrices différentes sont utilisées.

120. Procédé selon la revendication 1, dans lequel plus de 10^7 matrices différentes sont utilisées.

121. Procédé selon la revendication 1, dans lequel la pluralité de matrices différentes a pour résultat la formation d'une banque de différentes molécules matricées, chacune desdites molécules matricées étant connectée à la matrice spécifique qui a servi de matrice par la synthèse de ladite molécule.

122. Procédé selon la revendication 1, dans lequel la pluralité de matrices différentes a pour résultat la formation d'une banque de différentes molécules matricées, chacune desdites molécules matricées étant connectée à la matrice complémentaire spécifique qui a servi de matrice par la synthèse de ladite molécule.

123. Procédé selon l'une quelconque des revendications précédentes comprenant l'étape supplémentaire de libérer la matrice ou la matrice complémentaire de la molécule matricée, et d'obtenir une molécule matricée qui n'est pas liée à la matrice complémentaire ou à la matrice qui a servi de matrice par la synthèse de la molécule matricée.

124. Composition de différentes molécules matricées, dans laquelle chacune desdites molécules matricées est liée à la matrice complémentaire spécifique qui a servi de matrice par la synthèse de la molécule matricée, dans laquelle les molécules matricées ne sont pas des alpha-peptides, et dans laquelle la composition est obtenue selon le procédé de la revendication 122.

125.Composition selon la revendication 124, ladite composition comprenant une pluralité d'environ 10^3 molécules matricées différentes.

126.Composition selon la revendication 124, ladite composition comprenant une pluralité d'environ 10^4 molécules matricées différentes.

127.Composition selon la revendication 124, ladite composition comprenant une pluralité d'environ 10^5 molécules matricées différentes.

128.Composition selon la revendication 124, ladite composition comprenant une pluralité d'environ 10^6 molécules matricées différentes.

129.Composition selon la revendication 124, ladite composition comprenant une pluralité d'environ 10^7 molécules matricées différentes,

130.Composition selon la revendication 124, ladite composition comprenant une pluralité d'environ 10^8 molécules matricées différentes.

131.Composition selon la revendication 124, ladite composition comprenant une pluralité d'environ 10^9 molécules matricées différentes.

132.Composition selon la revendication 124, ladite composition comprenant une pluralité d'environ 10^{10} molécules matricées différentes.

133.Composition selon l'une quelconque de revendications 124 à 132 comprenant en outre les matrices qui ont servi de matrice par la synthèse des différentes molécules matricées, ou un sous-ensemble de celles-ci.

134.Composition selon la revendication 133, dans laquelle la molécule matricée est liée de manière covalente à la matrice qui a servi de matrice par la synthèse de la molécule matricée.

135.Composition selon la revendication 133, dans laquelle la molécule matricée est liée de manière non-covalente à la matrice qui a servi de matrice par la synthèse de la molécule matricée.

136.Composition selon la revendication 135, dans laquelle la liaison non-covalente implique une ou plusieurs liaisons sélectionnées parmi le groupe constitué des liaisons hydrogène, des liaisons van der Waals, et des liaisons ioniques.

137.Procédé selon l'une quelconque des revendications 1 à 123 comprenant en outre l'étape de criblage d'une composition de complexes bifonctionnels comprenant chacun une molécule matricée différente pour des molécules matricées ayant une activité prédéterminée spécifique, ledit procédé de criblage comprenant:

i) l'obtention d'une composition de différentes molécules matricées par le procédé selon l'une quelconque des revendications 1 à 123,

ii) l'exposition de la composition de différentes molécules matricées à des conditions ayant pour résultat un enrichissement des molécules matricées ayant l'activité prédéterminée spécifique.

138.Procédé selon la revendication 137 comprenant en outre l'étape d'amplification des molécules matricées de la composition enrichie, obtenant ainsi une seconde composition de molécules matricées.

139.Procédé selon la revendication 138, dans lequel les étapes d'exposition de la composition de différentes molécules matricées à des conditions ayant pour résultat un enrichissement des molécules matricées ayant l'activité prédéterminée et d'amplification des molécules matricées de la composition enrichie sont répétées.

140.Procédé selon la revendication 139, dans lequel lesdites étapes sont répétées au moins 2 fois.

141.Procédé selon la revendication 139, dans lequel lesdites étapes sont répétées au moins 3 fois.

142.Procédé selon la revendication 139, dans lequel lesdites étapes sont répétées au moins 5 fois.

143. Procédé selon l'une quelconque des revendications 139 à 142, dans lequel la répétition des étapes du procédé a pour résultat une composition encore enrichie de molécules matricées ayant l'activité prédéterminée spécifique.

144. Procédé selon la revendication 138, comprenant en outre l'étape de mutation des molécules matricées, dans lequel ladite mutagenèse peut être réalisée avant, en même temps que, ou après l'amplification des molécules matricées de la composition enrichie.

145. Procédé selon la revendication 144, dans lequel la mutagenèse est réalisée par mutagenèse aléatoire ou dirigée.

146. Procédé selon la revendication 138, dans lequel les molécules matricées de la composition enrichie sont amplifiées par un facteur allant de 10^1 à 10^{15} .

147. Procédé selon la revendication 137 comprenant en outre l'étape d'identification d'une molécule matricée ayant l'activité prédéterminée.

148. Procédé selon la revendication 147, dans lequel l'identification est réalisée en analysant physiquement la matrice et/ou la matrice complémentaire.

149. Procédé selon la revendication 137, dans lequel les molécules matricées de la fraction enrichie ayant l'activité prédéterminée sont obtenues par liaison à un partenaire de liaison immobilisé sur un support.

150. Procédé selon la revendication 137, dans lequel les molécules matricées de la fraction enrichie ayant l'activité prédéterminée sont obtenues par séparation électrophorétique, gel-filtration, immunoprécipitation, électrofocalisation, centrifugation, et immobilisation.

151. Procédé selon la revendication 137, dans lequel l'activité prédéterminée est une activité catalytique.

Addition to carbon-carbon multiple bonds

$\text{Z} = \text{H, Alkyl, Z, Ar}$
 $\text{Z}'' = \text{COOR, CHO, COR, CONR}''_2, \text{CN, NO}_2, \text{SOR, SO}_2\text{R, SO}_2\text{NR}''_2, \text{ect.}$
 $\text{Z}' = \text{Z}'' \quad \text{R} = \text{R}', = \text{R}'', = \text{Z}$

$\text{Z} = \text{H, Alkyl, Ar,}$
 $\text{Z}' = \text{Z'', Alkyl, Ar,}$
 $\text{Z} = \text{COOR, CHO, COR, CONR}''_2, \text{CN, NO}_2, \text{SOR, SO}_2\text{R, SO}_2\text{NR}''_2, \text{ect.}$

Cycloaddition to multiple bonds

$\text{Z} = \text{COOR, CHO, COR, COOH, COAr, CN, NO}_2,$
 $\text{Ar, CH}_2\text{OH, CH}_2\text{NH}_2, \text{CH}_2\text{CN, SOR, SO}_2\text{R, etc.}$
 $\text{R} = \text{H, Alkyl, Ar, Z} \quad \text{X} = \text{O, NR, CR}_2, \text{S,}$

Addition to carbon-hetero multiple bonds

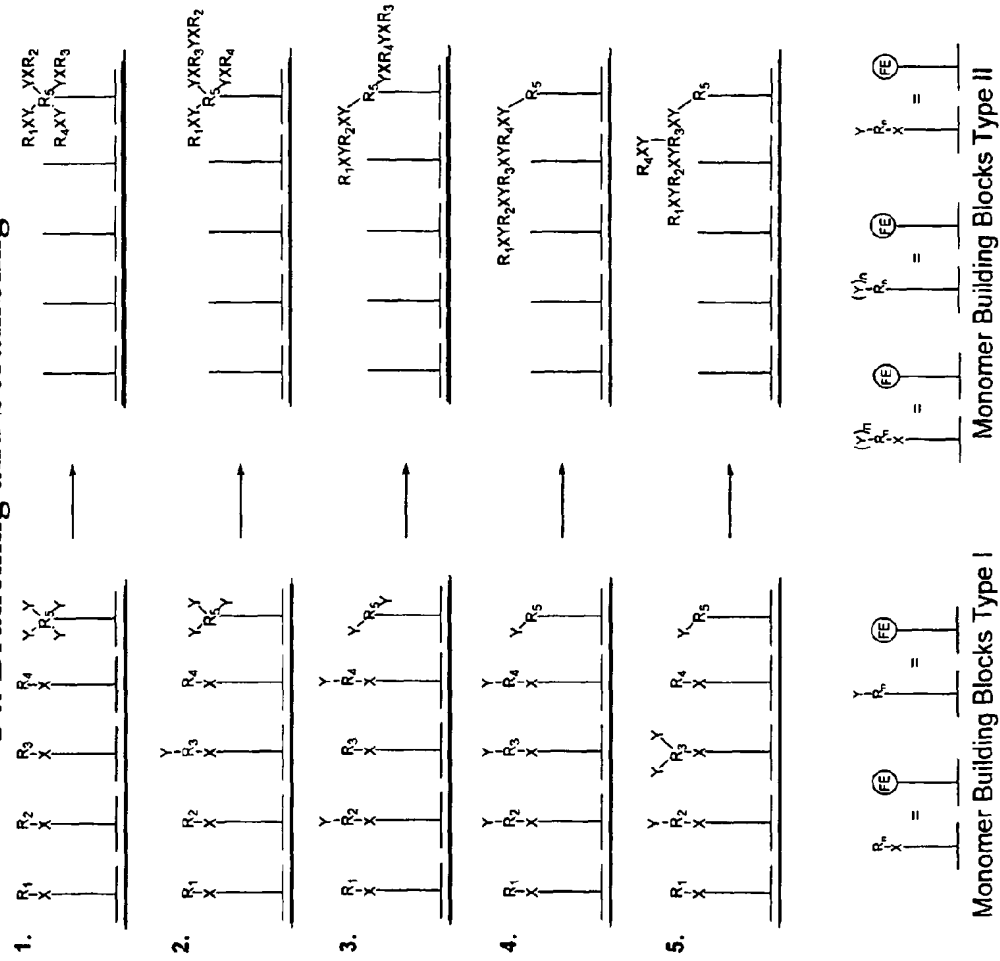

$\text{Z} = \text{COOR}, \text{CHO}, \text{COR}, \text{SOR}, \text{SO}_2\text{R}, \text{CN}, \text{NO}_2, \text{ect.}$
 $\text{R} = \text{R}', \text{H}, \text{Alkyl}, \text{Ar},$
 $\text{R}'' = \text{R}''', \text{H}, \text{Alkyl}, \text{COR},$
